Overall idea: take a standard receiving antenna, realize that the antenna currents generate their own fields, then conceptually shrink that antenna while adding some circuitry which keeps its field pattern strong at a 1/4-wave distance. You can shrink the antenna to any small size, yet if the antenna-generated field remains large, the received power will not decrease much. AM radio antennas the size of large molecules become possible, at least in theory. A desktop longwave antenna with the electrical size of a broadcasting tower becomes possible (although superconducting materials are probably required.)

Hello All,

I have the MFJ 9402 for 2M SSB. It's a great little rig, but the analog dial makes it difficult to duplicate returning to a given frequency, even the calling frequency at 144.2MHZ unless there's traffic there.

Anyone got a lead on a good digital freq readout that could be adapted to this rig?

Direct E Mail replies welcomed.

The trick is to use a laser printer to print on to Epson Photo Quality
paper, then iron it onto the PCB. Soak it in hot soapy water to remove
paper and leave toner behind. It works a treat.

Hi folks!
Couple weeks ago I'd bought Autek RF1 & RF5 for very reasonable price.
RF5 had some defects but now all OK. Unfortunately both units was
supplied without User Manuals.
I would be very obligated if somebody can supply me of manual's
electronic copy.
Another question - I need the schematic for Ameritron QSK-5. On the
website of manufacturer I'd find instruction only.
Thank you in advance,
Igor Dobrokhotov UN7GM

William - I have not followed this argument in detail, but you
might be interested in a fundamental theory which gives the
bandwidth of small antennas in terms of their size in wavelengths.
The theory, based on a transmitting antenna, establishes the stored
energy as a multiple of the radiated energy to derive a Q factor
which leads to an expression for the the bandwidth.
The paper, by Chu, is in J. Applied Physics, Dec. 1948, and the
theory gives an upper limit for bandwidth in terms of the radius of
the smallest sphere which can enclose the antenna, and it is
independent of the details of the particular antenna. A good
approximation from the theory, for a lossless antenna, is:
B/f0=250(r/lambda)^3
B is bandwidth, f0 is carrier frequency, r is the sphere radius
and lambda is the wavelength.
For a 150mm loopstick at 1MHz the bandwidth comes out at
0.004Hz from the formula BUT in practice there is sufficient
loss resistance present to raise the bandwidth to (say) 40kHz, a
factor of 10^7, whilst reducing the gain by 70dB. This is acceptable
because enough power is transmitted, and sufficient amplification is
present in the receivers, to make it acceptable. The theory might
provide guidance about the feasibility of atom-sized antennas.

I've wondered about this, too, but I haven't had time to try anything. Currently, I'm using the laser-printer method where the board graphic is printed on a laser-printer, and then the toner from the paper is thermally transferred to the board. It works, but it's a bit sensitive to board cleanness, toner density, iron temperature, etc. (Phase of the moon?)

Most of the plotters readily available now seem to want to move the paper to control one dimension, although the Roland mentioned later in this thread is an XY plotter which should work. Additionally, I used to have access to an ancient HP plotter which was a true XY plotter (I think it attached to an HP 9830 computer system, but it's been years ago since I last used it.).

One of the things I've considered is that instead of using ink, to modify an XY plotter to mount a light source where the pen fits. Then, it should be possible to place a photo-sensitized board on the plotter, and directly plot a photographic image on the board (Disconnect the pen up-down solenoid, and use that signal to turn the light source on and off.).

Selection of the appropriate light source might be a problem. I'm aware that there are UV LEDs available (UV laser diodes?). With the correct optics, this might get enough light onto the board to expose a photoresist, if a sensitive enough photoresist exists. Of course, it might be necessary to verify that the pen speed of the plotter is relatively constant.

Dave

P.S. Standard Disclaimer: I work for them, but I don't speak for them.

Wow! What a response. I guess this is an interesting topic.

I use a Roland Sketchmate which is a flatbed A4 plotter. I have machined out an old HP pen to accept the Black Staedtler Lumicolor permanent Overhead pens type S(313) and F (318) I find the ink is good at resisting the ferric chloride.
I use a programme called Proteus Lite (Labcenter.co.uk) and they have a neat plotter driver for this purpose. When setting up the 7475 emulation in windows It is essential to reduce the pen speed to 1 or 2 cm/sec if using S pens. I go up to 3 for F pens. This puts more ink on the board.

I like the idea about the optical plotting I will think about this. There are lots of IR diodes about are there UV ones?
Thanks folks for the contributions.

IMHO by far the easiest method is to use a flat bed pen plotter that will plot the circuit directly onto copper. I use a HP 7475A with the a pen modified to take a permanent marker. Staedtler Lumocolor 317 works O'K The software is Easytracks by Protel which is a DOS freeware program and works very well, drives the plotter without any problem.

I haven't done any in depth experimenting but the minimum track width is dependant upon the pen used. The thinnest I've tried is 'F' which gives a line about 12 thou thick.
It is best if the line is drawn twice over. This can be done by 'telling' the Easytraks program that the pen width is slightly less than the plot width, by a couple of thou'. The actual pen width must be wider than that defined to the program so that lines drawn for in-fill overlap.

Easytraks also allows the pen speed to be defined in inches/sec I've used 0.5 "/sec O'K. Its a case of juggling the three parameters, the actual pen width, what you 'tell' Easytraks the pen width is and how fast the pen/paper (pcb) is to move. Keeping in mind you dont want gaps between lines in the in-fill area's and double over drawing for the tracks. Laying the tracks twice on the drawing is another method as well as plotting the complete drawing twice. All these methods seem to produce a heavy enough ink deposit.

The neatest is to plot the complete drawing twice making shaw that the lines overlap in the in-fill areas.

I use double sided Sellotape to fix the copper board to a sheet of A4 paper, just a couple of pieces seem to work, no need to cover the whole board. My boards are small 4" X 2".

The Staedtler pen ink can be removed with acetone (nail polish remover).

As this is quick to do it's no problem to clean the ink off
and give it another try.

This cannot be true. Many photons, yes, many cycles, no.
The energy cant be stored over a period greater than the
frequency of the wave, otherwise, the modulations would be
washed out. In an amplifier, you would call the lack of
ability to change at the signal rate a slewing limitation.

> pointlike particles don't magically interact with EM
> waves, instead it is their surrounding fields which

No, the energy received by an antenna is exactly the interaction of
photon with a pointlike electron. The size of the antenna is what
determines how efficiently it provides electrons to cover the volume
of space in which that photon has a probability of being found.
A standard dipole just happens to meet this condition (along with
a couple of others). It doesnt have a monopoly on geometry. It just
happens to be particularly simple.

> That's why I keep saying that the FIELDS of the electrically
> short antenna are reaching out and grabbing EM waves. The

The fields cant do anything but move charges. If you can explain
it in that context, then you may be able to justify that statement,
but otherwise that statement is wrong.

> to punch a hole in the wavetrain of EM waves passing by.
> Do you object to this? If not, then why are electrically
> small resonant antennas (with their huge local fields)
> such a problem?

Because you are ignoring the antenna's and the rest of the system's
requirements for providing a signal from the currents produced by
radiation incident on the antenna.

> I think not. I think I'm unable to get my ideas across

In that case, try changing your viewpoint, because you aren't

making it clear that you are using the terminology in a way
that doesn't make your statements incompatible with the physics
you claim isnt in disagreement.

> If you are certain that a normal half-wave dipole can
> intercept EM waves without the dipole generating fields
> of its own, then we have a serious problem. If you

Of course there is a field. If there were not, no current
would flow, making it totally useless as an antenna. A charge
is accelerated by the incoming photon. Because it is displaced
from equilibrium, it produces forces on other charges and so
on. This is the definition of a current.

Right. If the energy is stored over many cycles, then fast
modulations will be washed out. That's what I'd expect.
The time constant for flourescent materials is long compared
to period of the waves involved. A resonant antenna would
act as if the incoming waves "pump it up" over time.

> In an amplifier, you would call the lack of
> ability to change at the signal rate a slewing limitation.

We're talking about the same thing, right? A high-Q tank
circuit connected to an electrically small antenna? We
shouldn't be suprised if it behaves differently than a simple
1/2-wave dipole. Because the tank circuit has high Q, won't
it respond slowly to changes? If the incoming wavetrain
begins abruptly, how could the high-Q tank circuit instantly
absorb enough energy to follow that leading edge of modulation?
And if the wavetrain suddenly ceases, why wouldn't the tank
circuit keep oscillating for many cycles? Because the tiny
antenna is weakly coupled to the incoming waves, won't the
AC voltage across the tank circuit change fairly slowly even
though the modulation is fast? (Hmmm. If the tank circuit had
infinite Q, maybe it would take infinite time for it to
aquire any energy from the EM waves.)

In the case of a real antenna like an AM radio loopstick,
it would make little difference if there was a significant
slewing limitation, since the audio bandwith is at least
50 times smaller than the carrier frequency. If it took
a 20-cycle time constant for the tank circuit to settle
to the instantaneous modulation envelope, the audio
fidelity wouldn't be changed much. Since the Q of a
realworld loopstick antenna isn't incredibly high, it

probably responds fairly quickly, rather than in hundreds
of cycles. It's a good point you've brought up though.
Raising the Q to enhance the "energy sucking" effect
might be good for S/N ratio, but bad for bandwidth and
audio fidelity of an AM signal.

Hi All,

I've been collecting valve based transmitters and receivers for a while and thoroughly enjoy them.

I've now reached the point where I want to have a go at build a valve transmitter, either CW or SSB.
Ideally I'd like it to be SSB on 160m as this is a great band for local nets.

Can anyone give me any clues as to where to start ?
Does anyone have any URL's with circuit diags on that I could use to build my first valve TX ?

Please reply to the group but also reply to me directly on the CC as my provider is a tad laxing
when it comes to news groups :)

Cheers!

Mike,

My advice, if you have never built anything from scratch before, would be to start simple. One of the classic one-tube CW transmitters using a crystal and a 6V6 or something along those lines. There's a lot of satisfaction in seeing it work, and using it on the air. Failing at a project too complex for a first try will tend to discourage you. The best matadors start with the small bulls and work their way up.

The best results I've had with sort of thing is laser print (or a copy if
you don't have a laser printer) onto transparancy film.

The hot iron (warm actually) transfer method worked better with the film
than with any of the papers I tried.

And it's not too hard to make simple double sided boards with this method
since you can see through the film and get things lined up easier.

Jim Pennino

>

Why? Flourescence occurs because the transitions from the
state emitting the light are inhibited from decaying but
are not the states excited by the incident radiation. If they
were the same state, from considerations of time-reversal, you
coupldn't populate the state faster than it decays. It occurs
from transitions like:

excitation

/ | fast transition to metastable state
/ --------
/ |
/ |
/ | slow transition
/ | inhibited by
------ -------- selection rules (J^pi, for example)
gs

There is no analogy in antenna. The resonance in an antenna means
X_C = C_L and the stored energy over a complete cycle is completely
determined by L and C.

> it respond slowly to changes? If the incoming wavetrain

Because the tank has a large Q, it's losses through the internal
resistances of its elements is small. That doesn't allow it to
accumulate energy, since you have to connect to it to (1) attach
the antenna, (2) arrange for charge to go in and out if you want

to do anything. With nothing but the antenna attached, guess what
happens with the energy stored in the tank each cycle? Remember,
it's a reversible process.

> begins abruptly, how could the high-Q tank circuit instantly
> absorb enough energy to follow that leading edge of modulation?

By instantly, I assume you mean the velocity of the propagation
in the conductor, i.e., the frequency doesnt hit any anomalous
dispersion (this ought to be good to about 10^14 Hz). So, below
frequencies where speed of light violations would have to be
considered, it does happen "instantly" for all practical purposes.

Why is the peak large: Z = R, not jwl + 1/jwc + R, since wL = 1/wc
at resonance. Since V = iZ if you assume i is the same for any
frequency (in direct contrast to the "energy sucking" stuff),
you can only develop a potential difference as large as Z permits.

Plot Z vs w. At the resonance pt, w_0, tt will look real similar
to Q which is a plot of w_0 vs \delta w.

> AC voltage across the tank circuit change fairly slowly even
> though the modulation is fast? (Hmmm. If the tank circuit had
> infinite Q, maybe it would take infinite time for it to
> aquire any energy from the EM waves.)
>

I think you might be getting the idea except that instead of thinking
Q think "energy sucking idea". The process has to be totally
reversible.

> Raising the Q to enhance the "energy sucking" effect
> might be good for S/N ratio, but bad for bandwidth and
> audio fidelity of an AM signal.

That's another reason the "energy sucking" cant be right. Increasing
the signal to noise always increases the bandwidth provided the
encoding is optimal (an encoding which depends upon certain spectral
characteristics of the noise, may of course be worse off with a better
S/N that also changes those characteristics, but that's a pathological
case which resides with the coding scheme)

1788. Trade?: (1)Micor, (2)Motrac, (1)Pullsar for....

Newsgroup: rec.radio.amateur.homebrew

Looking to trade:
1 Motorola Micor Tested Working W/ Control Head (Freuency Counter showed 800 mhz.)
1 Motorola Pulsar Tested Working W/ Control Head (Frequency Counter showed 150 mhz.)
2 Motorola Motracs Unknown Frequency Untested No Control Head

I was going to convert the 2 first ones for repeater use, but didnt want to attempt it in case I blow them up. So I will trade all 4 radios for a working Converted for Repeater use GE Master II or Motorola Micor on either 2 meters or 220mhz amateur bands ready to use, Controller Ready....

The Micor and Pulsar look in good shape and are working. The Motracs are ugly and untested because there is no control heads.

Here is the info for the radios:

Motorola Micor:
FCC XMTR DATA: CC5010
FCC RCVR DATA: RC0071
MODEL #: T45RTA6B00AA
SERIAL #: 439CDS1200

Motorola Pulsar
MODEL: T1776A
RCVR: RC0047
FCC TYPE: CC3225
SERIAL: RR6210

Motorola Motrac #1:
MODEL: U43HHT-11300
TRANS TYPE: CC3009
SERIAL#: E-14787

Motorola Motrac #2:
MODEL: T43MHT-1190C
TRANS TYPE: CC3059
CABLE TYPE: 2
SERIAL#: Not Visible

I would prefer a local trade (Redding, CA.) but will ship in the US.

Icom IC-230 with manual, mic and mobile bracket. not working correctly, VCO unlocks but in great cosmetic condition,, $30.00 Shipped

Browning Mark III Receiver, Browning Mark III AM Transmitter, Very Clean! and D104 Mic $250.00 Pic will be on the Website Soon !

Tram D201s, Both have unlocked VFO's, One has lower freqs with good AM and weak SSB the other has upper freqs with good AM and SSB. Both in good condition $250.00 Each

Penetrator HB-150 10/15/20/40 meter Mobile amplifier, 150 watts class AB1 Low drive input required, super clean! $150.00

Yamaha FG-460S-12S, 12 String Guitar, Beautiful guitar, near flawless, Gold hardware, Pearl inlay, Seymore Duncan Acoustic Pick-up, Hard Case $350.00

Hooker 10 meter Amplifier, 1 pill design, PEP and RMS mode, CW/AM/SSB, Preamplifer, Clean, still has factory seals $75.00

Pacifc Scientific / Superior Electric 2 Axis Servo System $250.00

Tram Diamond 60 AM/SSB Mobile, SIltronics Model 90 VFO -3 and Paradynamics Meter, All in good working condition $175.00

VHF Trielectric Amplifier 13.8 VDC As Is $40.00

Motorola UHF 13.8 VDC 450-470 Mhz Solid State Amplifier, clean!, Surplus, As Is $40.00

Alan K1313 10 meter Single Tube Modulator, 110 VAC, With Spare 6KG6 tube, New Russian tube installed, Spare is 90% or better, Clean and works Great! $150.00

Johnson Messenger 250 Base, With Original Box and Manual $75.00

Astatic 10DA Mic Head, Works and looks good, Missing the locking Ring but plugs right into a D104 Stand $30.00

Fentone 500C Studio dual crystal Mic Head On a TUG8 D104 Stand, Wired to a Demco Tube Modulator. Smooth Clear Audio! $200.00 Obo

Pentax K1000 35mm Camera, Wide and normal lens, 2x teleconverter. Cokin filter holder with flare guard. Several special effect Cokin Filters, polorizers and acessories, carrying case etc... $250.00 Obo

SBE Trinidad , 23 channel base CB, near perfect condition, original manual $70.00

Fluke 8050A Digital Desktop Multimeter, AC/Batt, needs new batt. but works great on AC $50.00

NF Circuit Design Block Model CR-116 Low Distortion Signal Generator, $125.00 Obo

Misc, Yaesu FT101 Components and parts, Misc untested boards, Email If you need something.

Electrovoice Mic.... See Website!

Misc 19" Racks..... Email for Details

Anybody know how to suppress noise generated from my KENWOOD MC-65 mic compressor in my car KENWOOD TM-241SQ.
I am very sure the noise is not from my RIG, It was no noise before I use MC-65.
My car is TOYOTA with diesel engine.
Appreciate your help
Thanks
Hartono Sudja, YD0KOR

> Very weird.

Look at the ubiquitous roof-top log-periodic TV antenna, you notice (for a 3 element anyways) a short dipole called a director, the receiving dipole that's 1/2 wave, and behind a long dipole called a reflector. The electricaly short dipole is capacitively reactive at the receiving frequency and bends radio waves into the receiving dipole. Behind the long reflector dipole acts inductive, and reflects energy back into the receiving dipole, which is purely resistive at the receiving frequency.

Nothing weird here. A constant phase shift occurs, reactance, when the dipole is long or short compared to the wavelength. It 'bends' or 'reflects' because the element is not loaded so it re-radiates energy. The superposition of the incident and radiated energy is what refracts or reflects. A field is required for this action.

But this is not the same as 'flux sucking'.

An atom has highly charged electrons or dipole moments. The electrons are mobile. When a photon's EM field is present, the electron and its charge and dipole moment move in the field to cancel it, and absorb the energy ending the photon if the electron gets stuck in a higher orbit, or re-radiating with a time delay when it falls to a lower orbit if the material is transparent. In high permiability and permitivity ceramics, the dipole

moment of the molecules are physicaly stressed by ambient flux and cancel it by displacing and concentrating the flux as stress in the ceramic.

An antenna is fixed and static. Currents only flow where conductors are. If you had an antenna that had a high static charge and magnetic moment, and was fluid, and virtualy massless, so it could re-configure itself in response to changes in an incident field, you would have an interesting antenna indeed.

Scott

>Just replace the flourescent lamp with a germicidal tube, the real trick is the 15 to 35 dollar price tag for the tube !!! the only real difference is the Quartz glass envelope instead of lime glass and no phosphor coating NB. this is not the Black Light Tube with a phosphor coating that glows at about 360 millimicrons !!! the Germicidal lamp is a low pressure mercury glow discharge that has a very strong line at 254 milimicrons and will cook your eyeballs at a normall working distance in about five minutes, but will not be obvious for an hour or two, feels like a very bad sunburn, only its is your eyes! that are burned. General Electric used to supply these lamps fourty years ago for Sterile rooms , this was before Laminar Flow Hoods became popular. this is the same lamp used for UV Eprom erasing, about 15 minutes at a distance of 1 or 2 inches from the tube. just keep the lamp covered with cardboard or metal to protect the eyes, short exposure to the bare lamp should be limited to ten seconds or less. you might try UV products, California for a web page ?

Really? What's its value? How did you measure it?

> That circular polarized laser beams attract? ;-)

Photon-photon interactions are a second-order effect in QED.
In the low-energy regime of this discussion, they can safely be
neglected.

In a nonlinear dispersive medium, certainly. But it's the
constitutive relation of the medium which produces the effect,
not any innate property of photons. In free space, superposition
still holds (apart from that 2nd-order QED caveat.)

1796. TEK-Plug_in PS

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-08 00:00:00 UTC
From: af389@lafn.ORG
Message-ID: <38C655C4.681750D1@lafn.org>
Source record: 62788

Need TEKTRONIX historians to help with this.
I am not certain such a product exists.
But it would be a helpful accessory.

I want to buy a cabinet with power supplies
that will accept TEK plug-in Verical Amps such as 7A19, etc. for 500,
5000 or 7000 TEK Scopes. This would be the equivalent of a TM501
but for the TEK 500, 5000 and 7000 accessories. The 7A19 could then
be operated as a standalone accessory without the scope mainframe,
output buffered, and fed to 50 ohm frequency counter, etc.

Do not know the model/part number.
Any hints will be gratefully accepted.
Thank you. 73, W6MIK

If there are currents in the dipole, then those currents
contribute to the (one) field.

> OK, but it is not obvious that a current alone can "draw in"
> the energy of an EM wave.

more oneness: currents and fields arise together.

> Thinking in terms of the field

Well, from the field theory point of view, it isn't
weird, it is necessary.

>

> small antenna's LC circuit would continue. (The antenna
> is too small to radiate much energy.)

The concept of dependence is readily extended for this.
You simply note that a transmitter that is switched on

and later switched off does not produce a single frequency
but rather produces a band of frequencies. The transient
response of the LC circuit is accounted for by the relative
phase
of those constituent frequencies. It doesn't really matter
in this case, since we can confine the discussion to the
steady state.

> The antenna's
> fields are not created by the incoming EM waves, instant
> by instant,

it only takes a little Fourier math to put it into
that framework.

> My previous reply was to Mr. Coffman, who insisted that
> an AC EM field could not deflect the Pointing vector of an
> EM wave (and therefore I am wrong about the ability of
> these tiny antennas to deflect EM energy into themselves.)

Again, it is wording. One field doesn't deflect another.
There is only one field and it deflects.

> > I think its just the way you tell it.
>
> Right! I'm speaking in clear terms, yet they are
> unconventional, so everyone seems to have objections.

You can use the word "spoon" to talk about a fork,
and if you don't realize that your are using a different
definition and we don't realize it also, its likely
that we would disagree and how a spoon works.

> Yet there is nothing wrong with my terminology, except
> that it is non-traditional.

Except that you are talking to people who use traditional
terminology.

> Yeah! And circuits connect with antennas in the realm of
> AC motors. ...

yes, Poynting vector approach applies to all

> large molecules become possible, at least in theory. A
> desktop longwave antenna with the electrical size of a
> broadcasting tower becomes possible (although

> superconducting materials are probably required.)

The reciprocal problem is easier to work. The mutual
inductance from a transmitter to a receiver is the same as
from the receiver to the transmitter. Let the
far away transmitter become a far away receiver. Let
the short dipole be a transmitter. It is trivial that if
the antenna is lossless and the matching components are
lossless that the antenna is 100% efficient, no matter
how small it is. Furthermore, the field from a dipole
of 0.01 wavelength is virtually the same as the field
from a 0.001 wavelength dipole. So, for the same power
in, I get the same signal at the far away receiver.

So, given lossless antenna materials and lossless
matching networks, all short dipoles are equal.

But to to consider some practical details, as our dipole
gets small, it gets thinner than skin depth. The resistance
at signal freq is the same as the dc resistance. As we
scale
the dipole down by a factor of 2, its length decreases by
two
and its cross section by 4 so that the dc resistance goes
up by 2. But, the radiation resistance goes down by a
factor
of four. At some point, it becomes very lossy.

Opinions expressed herein are my own and may not represent those of my employer.

I haven't read the paper, but I suspect that they put
more power into it than they pulled out of the incoming
wave.

>
> > My objection is one of emphasis. The way you have told it,
> > it sounds to me like you consider the source fields and the
> > antenna field to be two separate fields.
>
> But they are,

As I let the water out of my bath tub, I notice that there
there is a depression in the water level over the drain.
The
depression is really there and it is interesting and
deserves
some study, but I don't tend to think of that depression as
sucking water out of the tub and shoving it down the drain.
To me, your description of energy sucking sounds backward
in a similar sense.

But, consider this (I think you will like it).

If I wind a coil on a torroidal form and energize it
sinusoidal, and if I do an idea job, there is no
H or B field outside of the torroid. There is E, but no
H or B. I then run a wire down the middle and
connect the ends to a resister. I have made a
transformer. The resister absords power. But how can
the Poynting vector be non zero it there is no H or
B from the primary current? Easy, it comes from the
secondary current. So here is a case where the E
component of the field is attributed to source
currents and the H component is attributed to the
load current. And it works fine.

Why? Because there is only one field and Poynting
says P = E cross H. It doesn't say P = Esource cross
Hsource.

Opinions expressed herein are my own and may not represent those of my employer.

Have a look at:

http://www.thinktink.com/index.htm

There's a lot of stuff there on serious PC board prototyping, including instructions for making a good light box. (From the index page, select "go to page..." --> "Make your own gear," or just start directly at that page: http://www.thinktink.com/stack/volumes/voliii/homespun.htm)

There's also a page on the chemistry, care and feeding of a cupric chloride etch bath on http://www.dnai.com/~rexa/Projects/CuCl_ech.html, FWIW.

Cheers,
Tom

The 2SC1945 crosses to a NTE 236 it is a TO-220 case however
the lead configuration may be difference than a 2SC1945.

Let me know if you need the specs. I have them in the book.

NTE has a US number of 1 800 631 1250
201 748 5089
FAX is 201 748 6224

You may be refered to a dealer who will have to order this. I
used one of these in my ham rig once until I got the real thing.

1806. Question about replacing battery pack for HTX-202

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-09 00:00:00 UTC
From: Michael1998@webtv.net
Message-ID: <11790-38C85C2C-14@storefull-131.iap.bryant.webtv.net>
Source record: 62648

I have a Ni-Cd battery pack for an HTX-202 that I am trying to replace. Does anyone know where I may buy a replacement battery pack for the radio. I don't want to replace the whole rechargeable battery itself, I just need the Ni-Cd pack inside the case that has the four wires coming off of it that can be soldered into the battery assembly. On the battery pack, it says 600 mAh 7.2 Volts, and the maufacturer is a company called Saft. If anyone knows where I may find a replacement pack for the radio, please e-mail me directly. Thanks a lot!

I mean not weird in that linear superpostion of the vacuum is not affected.

> If that's not weird, then "energy sucking" isn't so weird

True. What single device can simultaneously generate a complementary field to an incident wave and absorb it too? It must occur with highly reactive elements in a near-field, because it will radiate power (by definition) in the far field.

Make Easy Money! Earn Over $10000 in weeks!

Just follow these simple instructions!

LOTS OF CASH, FAST - THIS IS A MAILING LIST PROGRAM -AND COMPLETELY =
LEGAL, THIS REALLY WORKS!! THIS REALLY CAN MAKE YOU EASY MONEY!!IT =
WORKS!!BUT YOU HAVE TO FOLLOW THIS LETTER FOR IT TO WORK!!!! A little =
while back, I was browsing through news groups, just like you are =
now,and came across an article similar to this that said you could make =
thousands of dollars within weeks with only an initial investment of =
6.00!So I thought,"Yeah ,right,this must be a scam", but like most of =
us, I was curious, so I kept reading. Anyway,it said that you send =
$1.00to each of the 6 names and address stated in the article. You then =
place your own name and address in the bottom of the list at #6, and =
post the article in at least 200 news groups.(There are thousands) No =
catch,that was it.So after thinking it over, and talking to a few people =
first,I thought about trying it. I figured what have I got to loose =
except 6 stamps and $6.00, right?Like most of us I was a little =
skeptical and worried about the legal aspects of it all.So I checked it =
out with the U.S. Post Office (1-800-725-2161) and they confirmed it was =
indeed legal! Then I invested the measly $6.00. Well GUESS =
WHAT!!...within 7 days,I started getting money in the mail ! I was =
shocked! I figured it would end soon,but the money just kept coming in. =
In my first, week I made about $25.00. By the end of the second week I =
had made a total of over $1,000.00! In the third week I had over =
$10,000.00 and it's still growing.This is now my fourth week and I have =
made a total of just over $42,000.00 and it is still coming in =
rapidly.It's certainly worth $6.00 and 6 stamps.Let me tell you how this =
works and most importantly, why it works...also make sure you print a =
copy of this article NOW,so you can get information off of it as you =
need it. Believe me, it does work!!
STEP 1:=20
Get 6 separate pieces of paper and write the following on each piece of =
paper"PLEASE PUT ME ON YOUR MAILING LIST".Now get 6 US $1.00 bills and =
place ONE inside each pieces of paper so the bill will not be seen =
through the envelope to prevent thievery. Next, place one paper in each =
of the 6 envelopes and seal them.Now,you should have 6 sealed =
envelopes,each with a piece of paper stating the above phrase,your name =
and address,and a $1.00 bill. What you are doing is creating a service =

by this. THIS IS ABSOLUTELY LEGAL! Mail the 6 envelopes to the following =
addresses:=20

#1) S.Bassett RR#1 Cannington,
Ontario,
Canada LOE 1EO=20

#2) Sharon=20
32 Sleepy Hollow LN,
Sicklerville,
NJ 08081=20

#3) Justin=20
3707 Crenna Ave.Concord,
CA 94519=20

#4) Chicollla=20
2 Oxford Mews,=20
Poquoson=20
VA 23662

#5)E. S.K. Law=20
30 Morewood Crescent,=20
Toronto, Ontario,=20
Canada M2K 1L7.

#6) Johny=20

2465 Middle RD

Columbia Falls MT, 59912

(Be sure to use the correct postage when mailing to the the states or =
out of the states)

STEP 2 :=20
Now take the #1 name off the list that you see above, move the other =
names up (6 becomes 5, 5 becomes 4, 4 becomes 3, etc.) add YOUR name as =
number 6 on the list.

STEP 3 :=20
Change anything you need to, but try to keep this article as close to =
original as possible.Now, post your amended article to at least 200 news =
groups. (I think there are close to 24,000 groups.) All you need is 200, =
but remember , the more you post the more money you =
make!---DIRECTIONS---HOW TO POST TO NEWS
GROUPS---=20
STEP 1) You don't need to re-type this entire letter to do your own =
posting. Simply put your cursor at the beginning of this letter and drag =
your cursor to the bottom of this document,and select 'copy' from the =
edit menu. This will copy the entire letter into the computers memory.=20
STEP 2) Open a blank "notepad" file under accessories in windows and =
place your cursor at the top of the blank page.From the 'edit' menu =
select 'paste'.This will paste a copy of the letter into notepad so that =

you can add your name to the list.
STEP 3) Save your new notepad file as a .txt file.If you want to do your =
in different sittings, you will always have this file to go back to.=20
STEP 4)Use Netscape or Internet explorer and try searching for various =
newsgroups (on-line forums, message boards, chat sites, discussions.)
STEP 5) Visit message boards and post this article as a new message by =
highlighting the text of this letter and selecting paste from the edit =
menu. Fill in the Subject,this will be the header everyone sees as then =
scroll through the list of postings in a particular group!**REMEMBER,THE =
MORE NEWSGROUPS YOU POST IN,THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE =
TO POST A MINIMUM OF 200**=20

That's it ! You will begin receiving money from around the world within =
days. You may eventually want to rent a P.O. Box due to the large amount =
of mail you will receive.If you wish to stay anonymous,you can invent a =
name to use, as long as the postman will deliver it. **JUST MAKE SURE =
ALL THE ADDRESSES ARE CORRECT.** Now the WHY part: Out of the 200 =
postings say I only receive 5 replies (a very low example). So then I =
made $5.00 with my name at #6 Now,each of the 5 persons who just sent me =
$1.00 make the MINIMUM 200 postings,each with my name at #5 and only 5 =
persons to each of the original 5, that is another $25.00 for me,now =
those 25 each make 200 MINIMUM posts with my name at #4 and only 5 =
replies each,I will bring in an additional $125.00! Now, those125 =
persons turn around and post the MINIMUM 200 with my name as #3 and I =
only receive 5 replies each,I will make an additional $625.00! OK,now =
here is the fun part,each one of those 625 persons post a MINIMUM of 200 =
letters with my name at #2 and they only receive 5 replies,that just =
made me $3,125.00!!! Those 3,125 persons will deliver this message to =
200 news groups with my name at #1 and if still 5 persons per 200 news =
groups react I will receive $15,625.00! With the original investment of =
only $6.00! AMAZING! When your name is no longer on the list, you just =
take the latest posting in the news groups and send out another $6.00 to =
names on the list, putting your name at number 6 again. And start =
posting again.The thing to remember is, do you realize that thousands of =
people all over the world are joining the internet and reading these =
articles, everday,JUST LIKE YOU ARE NOW!! So can you afford $6.00 and =
see if it really works?? I think so ... People have said,"What if the =
plan is played out and no one sends you the money? So what! What are the =
chances of that happening when there are tons of new honest users and =
new honest users who are joining the internet and newsgroups every day =
and are willing to give it a try? Estimates are at 20,000 to 50,000 new =
users,every day ,with thousands of those joining the actual internet. =
Remember,play FAIRLY and HONESTLY and this will work.=20

------=_NextPart_000_0041_01BF8933.E7240C60

charset="iso-8859-1"

2465 Middle RD

Columbia Falls MT, 59912

(Be sure to use the correct postage when mailing to the the states or =
out of the states)

STEP 2 :=20
Now take the #1 name off the list that you see above, move the other =
names up (6 becomes 5, 5 becomes 4, 4 becomes 3, etc.) add YOUR name as =
number 6 on the list.

STEP 3 :=20
Change anything you need to, but try to keep this article as close to =
original as possible.Now, post your amended article to at least 200 news =
groups. (I think there are close to 24,000 groups.) All you need is 200, =
but remember , the more you post the more money you =
make!---DIRECTIONS---HOW TO POST TO NEWS
GROUPS---=20
STEP 1) You don't need to re-type this entire letter to do your own =
posting. Simply put your cursor at the beginning of this letter and drag =
your cursor to the bottom of this document,and select 'copy' from the =
edit menu. This will copy the entire letter into the computers memory.=20
STEP 2) Open a blank "notepad" file under accessories in windows and =
place your cursor at the top of the blank page.From the 'edit' menu =
select 'paste'.This will paste a copy of the letter into notepad so that =

you can add your name to the list.
STEP 3) Save your new notepad file as a .txt file.If you want to do your =
in different sittings, you will always have this file to go back to.=20
STEP 4)Use Netscape or Internet explorer and try searching for various =
newsgroups (on-line forums, message boards, chat sites, discussions.)
STEP 5) Visit message boards and post this article as a new message by =
highlighting the text of this letter and selecting paste from the edit =
menu. Fill in the Subject,this will be the header everyone sees as then =
scroll through the list of postings in a particular group!**REMEMBER,THE =
MORE NEWSGROUPS YOU POST IN,THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE =
TO POST A MINIMUM OF 200**=20

That's it ! You will begin receiving money from around the world within =
days. You may eventually want to rent a P.O. Box due to the large amount =
of mail you will receive.If you wish to stay anonymous,you can invent a =
name to use, as long as the postman will deliver it. **JUST MAKE SURE =
ALL THE ADDRESSES ARE CORRECT.** Now the WHY part: Out of the 200 =
postings say I only receive 5 replies (a very low example). So then I =
made $5.00 with my name at #6 Now,each of the 5 persons who just sent me =
$1.00 make the MINIMUM 200 postings,each with my name at #5 and only 5 =
persons to each of the original 5, that is another $25.00 for me,now =
those 25 each make 200 MINIMUM posts with my name at #4 and only 5 =
replies each,I will bring in an additional $125.00! Now, those125 =
persons turn around and post the MINIMUM 200 with my name as #3 and I =
only receive 5 replies each,I will make an additional $625.00! OK,now =
here is the fun part,each one of those 625 persons post a MINIMUM of 200 =
letters with my name at #2 and they only receive 5 replies,that just =
made me $3,125.00!!! Those 3,125 persons will deliver this message to =
200 news groups with my name at #1 and if still 5 persons per 200 news =
groups react I will receive $15,625.00! With the original investment of =
only $6.00! AMAZING! When your name is no longer on the list, you just =
take the latest posting in the news groups and send out another $6.00 to =
names on the list, putting your name at number 6 again. And start =
posting again.The thing to remember is, do you realize that thousands of =
people all over the world are joining the internet and reading these =
articles, everday,JUST LIKE YOU ARE NOW!! So can you afford $6.00 and =
see if it really works?? I think so ... People have said,"What if the =
plan is played out and no one sends you the money? So what! What are the =
chances of that happening when there are tons of new honest users and =
new honest users who are joining the internet and newsgroups every day =
and are willing to give it a try? Estimates are at 20,000 to 50,000 new =
users,every day ,with thousands of those joining the actual internet. =
Remember,play FAIRLY and HONESTLY and this will work.=20

Make Easy Money! Earn Over $10000 in weeks!

Just follow these simple instructions!

LOTS OF CASH, FAST - THIS IS A MAILING LIST PROGRAM -AND COMPLETELY =
LEGAL,=20
THIS REALLY WORKS!! THIS REALLY CAN MAKE YOU EASY MONEY!!IT WORKS!!BUT =
YOU HAVE=20
TO FOLLOW THIS LETTER FOR IT TO WORK!!!! A little while back, I was =
browsing=20
through news groups, just like you are now,and came across an article =
similar to=20
this that said you could make thousands of dollars within weeks with =
only an=20
initial investment of 6.00!So I thought,"Yeah ,right,this must be a =
scam", but=20
like most of us, I was curious, so I kept reading. Anyway,it said that =
you send=20
$1.00to each of the 6 names and address stated in the article. You then =
place=20
your own name and address in the bottom of the list at #6, and post the =
article=20
in at least 200 news groups.(There are thousands) No catch,that was =
it.So after=20
thinking it over, and talking to a few people first,I thought about =
trying it. I=20
figured what have I got to loose except 6 stamps and $6.00, right?Like =
most of=20
us I was a little skeptical and worried about the legal aspects of it =
all.So I=20
checked it out with the U.S. Post Office (1-800-725-2161) and they =
confirmed it=20
was indeed legal! Then I invested the measly $6.00. Well GUESS =
WHAT!!...within 7=20
days,I started getting money in the mail ! I was shocked! I figured it =
would end=20
soon,but the money just kept coming in. In my first, week I made about =
$25.00.=20
By the end of the second week I had made a total of over $1,000.00! In =
the third=20
week I had over $10,000.00 and it's still growing.This is now my fourth =
week and=20
I have made a total of just over $42,000.00 and it is still coming in=20
rapidly.It's certainly worth $6.00 and 6 stamps.Let me tell you how this =
works=20
and most importantly, why it works...also make sure you print a copy of =
this=20
article NOW,so you can get information off of it as you need it. Believe =
me, it=20
does work!!
STEP 1:
Get 6 separate pieces of paper and write the=20
following on each piece of paper"PLEASE PUT ME ON YOUR MAILING LIST".Now =
get 6=20
US $1.00 bills and place ONE inside each pieces of paper so the bill =

will not be=20
seen through the envelope to prevent thievery. Next, place one paper in =
each of=20
the 6 envelopes and seal them.Now,you should have 6 sealed =
envelopes,each with a=20
piece of paper stating the above phrase,your name and address,and a =
$1.00 bill.=20
What you are doing is creating a service by this. THIS IS ABSOLUTELY =
LEGAL! Mail=20
the 6 envelopes to the following addresses:

#1) S.Bassett =
RR#1=20
Cannington,
Ontario,
Canada LOE 1EO

#2) Sharon
32 =
Sleepy=20
Hollow LN,
Sicklerville,
NJ 08081

#3) Justin
3707 =
Crenna=20
Ave.Concord,
CA 94519

#4) Chicollla
2 Oxford Mews, =

Poquoson=20

VA 23662

#5)E. S.K. Law
30 Morewood Crescent, =

Toronto,=20
Ontario,
Canada M2K 1L7.

#6) Johny

2465 Middle RD

Columbia Falls MT, 59912

(Be sure to use the correct postage when mailing to the the states or =
out of=20
the states)

STEP 2 :
Now take the #1 name off the list that you see above, =
move the=20
other names up (6 becomes 5, 5 becomes 4, 4 becomes 3, etc.) add YOUR =
name as=20
number 6 on the list.

STEP 3 :
Change anything you need to, =
but try=20
to keep this article as close to original as possible.Now, post your =
amended=20
article to at least 200 news groups. (I think there are close to 24,000 =
groups.)=20
All you need is 200, but remember , the more you post the more money you =

make!---DIRECTIONS---HOW TO POST TO NEWS
GROUPS---
STEP 1) You =
don't need=20
to re-type this entire letter to do your own posting. Simply put your =
cursor at=20
the beginning of this letter and drag your cursor to the bottom of this=20
document,and select 'copy' from the edit menu. This will copy the entire =
letter=20
into the computers memory.
STEP 2) Open a blank "notepad" file under =

accessories in windows and place your cursor at the top of the blank =
page.From=20
the 'edit' menu select 'paste'.This will paste a copy of the letter into =
notepad=20
so that you can add your name to the list.
STEP 3) Save your new =
notepad file=20
as a .txt file.If you want to do your in different sittings, you will =
always=20
have this file to go back to.
STEP 4)Use Netscape or Internet =
explorer and=20
try searching for various newsgroups (on-line forums, message boards, =
chat=20
sites, discussions.)
STEP 5) Visit message boards and post this =
article as a=20
new message by highlighting the text of this letter and selecting paste =
from the=20
edit menu. Fill in the Subject,this will be the header everyone sees as =
then=20
scroll through the list of postings in a particular group!**REMEMBER,THE =
MORE=20
NEWSGROUPS YOU POST IN,THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO =

POST A=20
MINIMUM OF 200**

That's it ! You will begin receiving money from =
around=20
the world within days. You may eventually want to rent a P.O. Box due to =
the=20
large amount of mail you will receive.If you wish to stay anonymous,you =
can=20
invent a name to use, as long as the postman will deliver it. **JUST =

Make Easy Money! Earn Over $10000 in weeks!

Just follow these simple instructions!

LOTS OF CASH, FAST - THIS IS A MAILING LIST PROGRAM -AND COMPLETELY =
LEGAL,=20
THIS REALLY WORKS!! THIS REALLY CAN MAKE YOU EASY MONEY!!IT WORKS!!BUT =
YOU HAVE=20
TO FOLLOW THIS LETTER FOR IT TO WORK!!!! A little while back, I was =
browsing=20
through news groups, just like you are now,and came across an article =
similar to=20
this that said you could make thousands of dollars within weeks with =
only an=20
initial investment of 6.00!So I thought,"Yeah ,right,this must be a =
scam", but=20
like most of us, I was curious, so I kept reading. Anyway,it said that =
you send=20
$1.00to each of the 6 names and address stated in the article. You then =
place=20
your own name and address in the bottom of the list at #6, and post the =
article=20
in at least 200 news groups.(There are thousands) No catch,that was =
it.So after=20
thinking it over, and talking to a few people first,I thought about =
trying it. I=20
figured what have I got to loose except 6 stamps and $6.00, right?Like =
most of=20
us I was a little skeptical and worried about the legal aspects of it =
all.So I=20
checked it out with the U.S. Post Office (1-800-725-2161) and they =
confirmed it=20
was indeed legal! Then I invested the measly $6.00. Well GUESS =
WHAT!!...within 7=20
days,I started getting money in the mail ! I was shocked! I figured it =
would end=20
soon,but the money just kept coming in. In my first, week I made about =
$25.00.=20
By the end of the second week I had made a total of over $1,000.00! In =
the third=20
week I had over $10,000.00 and it's still growing.This is now my fourth =
week and=20
I have made a total of just over $42,000.00 and it is still coming in=20
rapidly.It's certainly worth $6.00 and 6 stamps.Let me tell you how this =
works=20
and most importantly, why it works...also make sure you print a copy of =
this=20
article NOW,so you can get information off of it as you need it. Believe =
me, it=20
does work!!
STEP 1:
Get 6 separate pieces of paper and write the=20
following on each piece of paper"PLEASE PUT ME ON YOUR MAILING LIST".Now =
get 6=20
US $1.00 bills and place ONE inside each pieces of paper so the bill =

will not be=20
seen through the envelope to prevent thievery. Next, place one paper in =
each of=20
the 6 envelopes and seal them.Now,you should have 6 sealed =
envelopes,each with a=20
piece of paper stating the above phrase,your name and address,and a =
$1.00 bill.=20
What you are doing is creating a service by this. THIS IS ABSOLUTELY =
LEGAL! Mail=20
the 6 envelopes to the following addresses:

#1) S.Bassett =
RR#1=20
Cannington,
Ontario,
Canada LOE 1EO

#2) Sharon
32 =
Sleepy=20
Hollow LN,
Sicklerville,
NJ 08081

#3) Justin
3707 =

(Be sure to use the correct postage when mailing to the the states or =
out of=20
the states)

STEP 2 :
Now take the #1 name off the list that you see above, =
move the=20
other names up (6 becomes 5, 5 becomes 4, 4 becomes 3, etc.) add YOUR =
name as=20
number 6 on the list.

STEP 3 :
Change anything you need to, =
but try=20
to keep this article as close to original as possible.Now, post your =
amended=20
article to at least 200 news groups. (I think there are close to 24,000 =
groups.)=20
All you need is 200, but remember , the more you post the more money you =

make!---DIRECTIONS---HOW TO POST TO NEWS
GROUPS---
STEP 1) You =
don't need=20
to re-type this entire letter to do your own posting. Simply put your =
cursor at=20
the beginning of this letter and drag your cursor to the bottom of this=20
document,and select 'copy' from the edit menu. This will copy the entire =
letter=20
into the computers memory.
STEP 2) Open a blank "notepad" file under =

accessories in windows and place your cursor at the top of the blank =
page.From=20
the 'edit' menu select 'paste'.This will paste a copy of the letter into =
notepad=20
so that you can add your name to the list.
STEP 3) Save your new =
notepad file=20
as a .txt file.If you want to do your in different sittings, you will =
always=20
have this file to go back to.
STEP 4)Use Netscape or Internet =
explorer and=20
try searching for various newsgroups (on-line forums, message boards, =
chat=20
sites, discussions.)
STEP 5) Visit message boards and post this =
article as a=20
new message by highlighting the text of this letter and selecting paste =
from the=20
edit menu. Fill in the Subject,this will be the header everyone sees as =
then=20
scroll through the list of postings in a particular group!**REMEMBER,THE =
MORE=20
NEWSGROUPS YOU POST IN,THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO =

POST A=20
MINIMUM OF 200**

That's it ! You will begin receiving money from =
around=20
the world within days. You may eventually want to rent a P.O. Box due to =
the=20
large amount of mail you will receive.If you wish to stay anonymous,you =
can=20
invent a name to use, as long as the postman will deliver it. **JUST =
MAKE SURE=20
ALL THE ADDRESSES ARE CORRECT.** Now the WHY part: Out of the 200 =
postings say I=20
only receive 5 replies (a very low example). So then I made $5.00 with =
my name=20
at #6 Now,each of the 5 persons who just sent me $1.00 make the MINIMUM =
200=20
postings,each with my name at #5 and only 5 persons to each of the =
original 5,=20
that is another $25.00 for me,now those 25 each make 200 MINIMUM posts =
with my=20
name at #4 and only 5 replies each,I will bring in an additional =
$125.00! Now,=20
those125 persons turn around and post the MINIMUM 200 with my name as #3 =
and I=20
only receive 5 replies each,I will make an additional $625.00! OK,now =
here is=20
the fun part,each one of those 625 persons post a MINIMUM of 200 letters =
with my=20
name at #2 and they only receive 5 replies,that just made me =
$3,125.00!!! Those=20
3,125 persons will deliver this message to 200 news groups with my name =
at #1=20
and if still 5 persons per 200 news groups react I will receive =
$15,625.00! With=20
the original investment of only $6.00! AMAZING! When your name is no =
longer on=20
the list, you just take the latest posting in the news groups and send =
out=20
another $6.00 to names on the list, putting your name at number 6 again. =
And=20
start posting again.The thing to remember is, do you realize that =
thousands of=20
people all over the world are joining the internet and reading these =
articles,=20
everday,JUST LIKE YOU ARE NOW!! So can you afford $6.00 and see if it =
really=20
works?? I think so ... People have said,"What if the plan is played out =
and no=20
one sends you the money? So what! What are the chances of that happening =

```
when=20
there are tons of new honest users and new honest users who are joining =
the=20
internet and newsgroups every day and are willing to give it a try? =
Estimates=20
are at 20,000 to 50,000 new users,every day ,with thousands of those =
joining the=20
actual internet. Remember,play FAIRLY and HONESTLY and this will work. =

Make Easy Money! Earn Over $10000 in weeks!

Just follow these simple instructions!

LOTS OF CASH, FAST - THIS IS A MAILING LIST PROGRAM -AND COMPLETELY =
LEGAL, THIS REALLY WORKS!! THIS REALLY CAN MAKE YOU EASY MONEY!!IT =
WORKS!!BUT YOU HAVE TO FOLLOW THIS LETTER FOR IT TO WORK!!!! A little =
while back, I was browsing through news groups, just like you are =
now,and came across an article similar to this that said you could make =
thousands of dollars within weeks with only an initial investment of =
6.00!So I thought,"Yeah ,right,this must be a scam", but like most of =
us, I was curious, so I kept reading. Anyway,it said that you send =
$1.00to each of the 6 names and address stated in the article. You then =
place your own name and address in the bottom of the list at #6, and =
post the article in at least 200 news groups.(There are thousands) No =
catch,that was it.So after thinking it over, and talking to a few people =
first,I thought about trying it. I figured what have I got to loose =
except 6 stamps and $6.00, right?Like most of us I was a little =
skeptical and worried about the legal aspects of it all.So I checked it =
out with the U.S. Post Office (1-800-725-2161) and they confirmed it was =
indeed legal! Then I invested the measly $6.00. Well GUESS =
WHAT!!...within 7 days,I started getting money in the mail ! I was =
shocked! I figured it would end soon,but the money just kept coming in. =
In my first, week I made about $25.00. By the end of the second week I =
had made a total of over $1,000.00! In the third week I had over =
$10,000.00 and it's still growing.This is now my fourth week and I have =
made a total of just over $42,000.00 and it is still coming in =
rapidly.It's certainly worth $6.00 and 6 stamps.Let me tell you how this =
works and most importantly, why it works...also make sure you print a =
copy of this article NOW,so you can get information off of it as you =
need it. Believe me, it does work!!
STEP 1:=20
Get 6 separate pieces of paper and write the following on each piece of =
paper"PLEASE PUT ME ON YOUR MAILING LIST".Now get 6 US $1.00 bills and =
place ONE inside each pieces of paper so the bill will not be seen =
through the envelope to prevent thievery. Next, place one paper in each =
of the 6 envelopes and seal them.Now,you should have 6 sealed =
envelopes,each with a piece of paper stating the above phrase,your name =
and address,and a $1.00 bill. What you are doing is creating a service =
```

by this. THIS IS ABSOLUTELY LEGAL! Mail the 6 envelopes to the following =
addresses:=20

#1) S.Bassett RR#1 Cannington,
Ontario,
Canada LOE 1EO=20

#2) Sharon=20
32 Sleepy Hollow LN,
Sicklerville,
NJ 08081=20

#3) Justin=20
3707 Crenna Ave.Concord,
CA 94519=20

#4) Chicollla=20
2 Oxford Mews,=20
Poquoson=20
VA 23662

#5)E. S.K. Law=20
30 Morewood Crescent,=20
Toronto, Ontario,=20
Canada M2K 1L7.

#6) Johny=20

2465 Middle RD

Columbia Falls MT, 59912

(Be sure to use the correct postage when mailing to the the states or =
out of the states)

STEP 2 :=20
Now take the #1 name off the list that you see above, move the other =
names up (6 becomes 5, 5 becomes 4, 4 becomes 3, etc.) add YOUR name as =
number 6 on the list.

STEP 3 :=20
Change anything you need to, but try to keep this article as close to =
original as possible.Now, post your amended article to at least 200 news =
groups. (I think there are close to 24,000 groups.) All you need is 200, =
but remember , the more you post the more money you =
make!---DIRECTIONS---HOW TO POST TO NEWS
GROUPS---=20
STEP 1) You don't need to re-type this entire letter to do your own =
posting. Simply put your cursor at the beginning of this letter and drag =
your cursor to the bottom of this document,and select 'copy' from the =
edit menu. This will copy the entire letter into the computers memory.=20
STEP 2) Open a blank "notepad" file under accessories in windows and =
place your cursor at the top of the blank page.From the 'edit' menu =
select 'paste'.This will paste a copy of the letter into notepad so that =

you can add your name to the list.
STEP 3) Save your new notepad file as a .txt file.If you want to do your =
in different sittings, you will always have this file to go back to.=20
STEP 4)Use Netscape or Internet explorer and try searching for various =
newsgroups (on-line forums, message boards, chat sites, discussions.)
STEP 5) Visit message boards and post this article as a new message by =
highlighting the text of this letter and selecting paste from the edit =
menu. Fill in the Subject,this will be the header everyone sees as then =
scroll through the list of postings in a particular group!**REMEMBER,THE =
MORE NEWSGROUPS YOU POST IN,THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE =
TO POST A MINIMUM OF 200**=20

That's it ! You will begin receiving money from around the world within =
days. You may eventually want to rent a P.O. Box due to the large amount =
of mail you will receive.If you wish to stay anonymous,you can invent a =
name to use, as long as the postman will deliver it. **JUST MAKE SURE =
ALL THE ADDRESSES ARE CORRECT.** Now the WHY part: Out of the 200 =
postings say I only receive 5 replies (a very low example). So then I =
made $5.00 with my name at #6 Now,each of the 5 persons who just sent me =
$1.00 make the MINIMUM 200 postings,each with my name at #5 and only 5 =
persons to each of the original 5, that is another $25.00 for me,now =
those 25 each make 200 MINIMUM posts with my name at #4 and only 5 =
replies each,I will bring in an additional $125.00! Now, those125 =
persons turn around and post the MINIMUM 200 with my name as #3 and I =
only receive 5 replies each,I will make an additional $625.00! OK,now =
here is the fun part,each one of those 625 persons post a MINIMUM of 200 =
letters with my name at #2 and they only receive 5 replies,that just =
made me $3,125.00!!! Those 3,125 persons will deliver this message to =
200 news groups with my name at #1 and if still 5 persons per 200 news =
groups react I will receive $15,625.00! With the original investment of =
only $6.00! AMAZING! When your name is no longer on the list, you just =
take the latest posting in the news groups and send out another $6.00 to =
names on the list, putting your name at number 6 again. And start =
posting again.The thing to remember is, do you realize that thousands of =

only receive 5 replies each,I will make an additional $625.00! OK,now =
here is the fun part,each one of those 625 persons post a MINIMUM of 200 =
letters with my name at #2 and they only receive 5 replies,that just =
made me $3,125.00!!! Those 3,125 persons will deliver this message to =
200 news groups with my name at #1 and if still 5 persons per 200 news =
groups react I will receive $15,625.00! With the original investment of =
only $6.00! AMAZING! When your name is no longer on the list, you just =
take the latest posting in the news groups and send out another $6.00 to =
names on the list, putting your name at number 6 again. And start =
posting again.The thing to remember is, do you realize that thousands of =
people all over the world are joining the internet and reading these =
articles, everday,JUST LIKE YOU ARE NOW!! So can you afford $6.00 and =
see if it really works?? I think so ... People have said,"What if the =
plan is played out and no one sends you the money? So what! What are the =
chances of that happening when there are tons of new honest users and =
new honest users who are joining the internet and newsgroups every day =
and are willing to give it a try? Estimates are at 20,000 to 50,000 new =
users,every day ,with thousands of those joining the actual internet. =
Remember,play FAIRLY and HONESTLY and this will work.=20

------=_NextPart_000_004E_01BF8933.EB43F4E0

charset="iso-8859-1"

Make Easy Money! Earn Over $10000 in weeks!

Just follow these simple instructions!

LOTS OF CASH, FAST - THIS IS A MAILING LIST PROGRAM -AND COMPLETELY =
LEGAL,=20
THIS REALLY WORKS!! THIS REALLY CAN MAKE YOU EASY MONEY!!IT WORKS!!BUT =
YOU HAVE=20
TO FOLLOW THIS LETTER FOR IT TO WORK!!!! A little while back, I was =
browsing=20
through news groups, just like you are now,and came across an article =
similar to=20
this that said you could make thousands of dollars within weeks with =
only an=20
initial investment of 6.00!So I thought,"Yeah ,right,this must be a =
scam", but=20
like most of us, I was curious, so I kept reading. Anyway,it said that =
you send=20
$1.00to each of the 6 names and address stated in the article. You then =
place=20
your own name and address in the bottom of the list at #6, and post the =
article=20
in at least 200 news groups.(There are thousands) No catch,that was =
it.So after=20
thinking it over, and talking to a few people first,I thought about =
trying it. I=20
figured what have I got to loose except 6 stamps and $6.00, right?Like =
most of=20
us I was a little skeptical and worried about the legal aspects of it =
all.So I=20
checked it out with the U.S. Post Office (1-800-725-2161) and they =
confirmed it=20
was indeed legal! Then I invested the measly $6.00. Well GUESS =
WHAT!!...within 7=20
days,I started getting money in the mail ! I was shocked! I figured it =
would end=20
soon,but the money just kept coming in. In my first, week I made about =
$25.00.=20
By the end of the second week I had made a total of over $1,000.00! In =
the third=20
week I had over $10,000.00 and it's still growing.This is now my fourth =
week and=20
I have made a total of just over $42,000.00 and it is still coming in=20
rapidly.It's certainly worth $6.00 and 6 stamps.Let me tell you how this =
works=20
and most importantly, why it works...also make sure you print a copy of =
this=20
article NOW,so you can get information off of it as you need it. Believe =
me, it=20
does work!!
STEP 1:
Get 6 separate pieces of paper and write the=20
following on each piece of paper"PLEASE PUT ME ON YOUR MAILING LIST".Now =
get 6=20
US $1.00 bills and place ONE inside each pieces of paper so the bill =

will not be=20
seen through the envelope to prevent thievery. Next, place one paper in =
each of=20
the 6 envelopes and seal them.Now,you should have 6 sealed =
envelopes,each with a=20
piece of paper stating the above phrase,your name and address,and a =
$1.00 bill.=20
What you are doing is creating a service by this. THIS IS ABSOLUTELY =
LEGAL! Mail=20
the 6 envelopes to the following addresses:

#1) S.Bassett =
RR#1=20
Cannington,
Ontario,
Canada LOE 1EO

#2) Sharon
32 =
Sleepy=20
Hollow LN,
Sicklerville,
NJ 08081

#3) Justin
3707 =
Crenna=20
Ave.Concord,
CA 94519

#4) Chicollla
2 Oxford Mews, =

Poquoson=20

VA 23662

#5)E. S.K. Law
30 Morewood Crescent, =

Toronto,=20
Ontario,
Canada M2K 1L7.

#6) Johny

2465 Middle RD

Columbia Falls MT, 59912

(Be sure to use the correct postage when mailing to the the states or =
out of=20
the states)

STEP 2 :
Now take the #1 name off the list that you see above, =
move the=20
other names up (6 becomes 5, 5 becomes 4, 4 becomes 3, etc.) add YOUR =
name as=20
number 6 on the list.

STEP 3 :
Change anything you need to, =
but try=20
to keep this article as close to original as possible.Now, post your =
amended=20
article to at least 200 news groups. (I think there are close to 24,000 =
groups.)=20
All you need is 200, but remember , the more you post the more money you =

make!---DIRECTIONS---HOW TO POST TO NEWS
GROUPS---
STEP 1) You =
don't need=20
to re-type this entire letter to do your own posting. Simply put your =
cursor at=20
the beginning of this letter and drag your cursor to the bottom of this=20
document,and select 'copy' from the edit menu. This will copy the entire =
letter=20
into the computers memory.
STEP 2) Open a blank "notepad" file under =

accessories in windows and place your cursor at the top of the blank =
page.From=20
the 'edit' menu select 'paste'.This will paste a copy of the letter into =
notepad=20
so that you can add your name to the list.
STEP 3) Save your new =
notepad file=20
as a .txt file.If you want to do your in different sittings, you will =
always=20
have this file to go back to.
STEP 4)Use Netscape or Internet =
explorer and=20
try searching for various newsgroups (on-line forums, message boards, =
chat=20
sites, discussions.)
STEP 5) Visit message boards and post this =
article as a=20
new message by highlighting the text of this letter and selecting paste =
from the=20
edit menu. Fill in the Subject,this will be the header everyone sees as =
then=20
scroll through the list of postings in a particular group!**REMEMBER,THE =
MORE=20
NEWSGROUPS YOU POST IN,THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO =

POST A=20
MINIMUM OF 200**

That's it ! You will begin receiving money from =
around=20
the world within days. You may eventually want to rent a P.O. Box due to =
the=20
large amount of mail you will receive.If you wish to stay anonymous,you =
can=20
invent a name to use, as long as the postman will deliver it. **JUST =
MAKE SURE=20
ALL THE ADDRESSES ARE CORRECT.** Now the WHY part: Out of the 200 =
postings say I=20
only receive 5 replies (a very low example). So then I made $5.00 with =
my name=20
at #6 Now,each of the 5 persons who just sent me $1.00 make the MINIMUM =
200=20
postings,each with my name at #5 and only 5 persons to each of the =
original 5,=20
that is another $25.00 for me,now those 25 each make 200 MINIMUM posts =
with my=20
name at #4 and only 5 replies each,I will bring in an additional =
$125.00! Now,=20
those125 persons turn around and post the MINIMUM 200 with my name as #3 =
and I=20
only receive 5 replies each,I will make an additional $625.00! OK,now =
here is=20
the fun part,each one of those 625 persons post a MINIMUM of 200 letters =
with my=20
name at #2 and they only receive 5 replies,that just made me =
$3,125.00!!! Those=20
3,125 persons will deliver this message to 200 news groups with my name =
at #1=20
and if still 5 persons per 200 news groups react I will receive =
$15,625.00! With=20
the original investment of only $6.00! AMAZING! When your name is no =
longer on=20
the list, you just take the latest posting in the news groups and send =
out=20
another $6.00 to names on the list, putting your name at number 6 again. =
And=20
start posting again.The thing to remember is, do you realize that =
thousands of=20
people all over the world are joining the internet and reading these =
articles,=20
everday,JUST LIKE YOU ARE NOW!! So can you afford $6.00 and see if it =
really=20
works?? I think so ... People have said,"What if the plan is played out =
and no=20
one sends you the money? So what! What are the chances of that happening =

```
when=20
there are tons of new honest users and new honest users who are joining =
the=20
internet and newsgroups every day and are willing to give it a try? =
Estimates=20
are at 20,000 to 50,000 new users,every day ,with thousands of those =
joining the=20
actual internet. Remember,play FAIRLY and HONESTLY and this will work. =

If that's not weird, then "energy sucking" isn't so weird
either, in my opinion. If the induced V and I on the
director element causes energy to be "lensed" towards
the active element, and if the fields generated by the
director are the cause... then if this whole process
could be performed by a single object (being director
and receiver simultaneously), then we'd have an
"energy sucking" device.

1815. Combination AM/FM detector

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-09 00:00:00 UTC
From: dr.dongle@juno.com
Message-ID: <8a75in$mg6$1@nnrp1.deja.com>
Source record: 62715

I'm home brewing a 50-900 Mhz reciever similar to the one in the current issue of 73 magizene. I have a nice Sony digital tuning varactor tuner, in which I have disabled the control/synth chip and will control tuning with a pot to the varactor ckt. The original IF is a second modual with a 1 chip combined video/IF and Sound/IF with a 4.5 Mhz filter between the two sections of the chip. The 41 Mhz video carrer normaly acts as a mixer oscilator input for the sound IF. There is also a 45 Mhz SAW filter (wide band) between the tuner and the IF chip. I would replace the SAW filter with a nerrow band 45 Mhz filter (15 K), and install a FET buffer between the filter and the IF amp input.
Next I would replace the 4.5 Mhz Ceramic filter between the Video/IF and Sound/IF with a SA 612 Mixer IC and use a mixer oscilator frequency of about +/- 44 Mhz.
All this (I think) should render a combination of an AM output from the video output and an FM output from the sound output.

Now, can any one find a hole in my plan and if so what is it and can it be easly fixed?

My other option is to use the 45 Mhz nerrow band filter, a buffer fet, a 612 to convert the 45 Mhz IF to 10.7 Mhz for FM with a FM detector chip and add a second 612 to convert the 10.7 to 455 Khz for AM, with a third 612 as a 445 Khz mixer for SSB.

All constructive input appricated.

I was under the impression that some fluorescence didn't
involve metastable states. I was thinking in terms of
an atom with a narrow absorbtion band having a small
probability of absorbing a photon (which would lead to
a long "pumping up" time) and a small probability of
emitting one (which would give a long decay time once
the incoming radiation ceased.) This would be analogous
to a resonator which takes many cycles to aquire energy
from a wavetrain, and many cycles to decay again.

what
> happens with the energy stored in the tank each cycle? Remember,
> it's a reversible process.

I understand what you're thinking (I think). If you're right,
then the short antenna would radiate energy as fast as it
absorbed it, and the presence of the resonant circuit would
not change this.

> I think you might be getting the idea except that instead of
thinking
> Q think "energy sucking idea". The process has to be totally
> reversible.

THERE'S a key point. If my understanding of the "energy sucking" mechanism is correct, then because the process involves interaction between the incoming EM waves and the fields generated by the resonator, it is NOT reversible, and the time constant for intercepting energy is shorter than the time constant for losses by radiation from the antenna. There would be an analog for Stimulated Emission: if the phase of the incoming waves were to shift 180deg, then any stored energy in the resonator would be "anti-sucked" and would dump out faster than it would ordinarily radiate.

> > Raising the Q to enhance the "energy sucking" effect
> > might be good for S/N ratio, but bad for bandwidth and
> > audio fidelity of an AM signal.
>
> That's another reason the "energy sucking" cant be right.

Slightly separate topic: does a resonant antenna receive more energy than a non-resonant antenna of similar geometery? Does the presence of a tank circuit actually change the effective area of a loop antenna, yes or no? In other words, is there evidence that SOMETHING occurs, even if it might not be exactly what I am discussing?

If you insist that "energy sucking" cannot exist on theoretical grounds, but if an ACTUAL ANTENNA does receive significantly more energy when it's part of a resonant circuit, then experiment beats theory.

I don't have reference books which discuss this, but earlier messages have mentioned that the presence of a tuned circuit DOES increase the effective area significantly. If they had not, and if those two physicist groups had not published papers about the topic, then I would be far less confident about the existence of the phenomenon.

Speaking of experiment. If I have time in the future, I'll try measuring the attack time of a resonant loop antenna receiving a carrier from a distant transmitter. If an AM signal can create a couple of volts on it, then a fast switch and a scope should let me watch as stored energy ramps up. (Short the capacitor, then suddenly remove the short and see if it ramps up over many cycles.) Hey, I can even throw a capacitance across it afterwards, to detune it so it ramps back down again.

Good. I dont expect you to find it and this is as good a group as any
to post to for an answer, which is - photons do not have a maagnetic
moment. Mainly, because they aren't charged. They aren't charged, because
that would really screw up qed. If photons had magnetic moments, one could
observe effects of the usual m\cdot B, variety. They do have a spin
angular momentum, though and it happens to be 1. However, spin alone doth
not a magnetic moment generate. The true skeptic may wish perform an
experiment though. Take the plane polarized light from a laser and shine
it down a solenoid. Several days of sleep deprivation might convince one
that the plane of polarization rotated about the axis of the solenoid.
Another day or so awake, and a dubious non-zero result for the amount
of bend one gets from a magnet held next to a flashlight might emerge.
Finally, one may deduce a limit on the magnetic moment and the charge
(B\rho = p/q ; \rho = radius of curvature) and consider investing in a
Berlitz book of swedish phrases for the black-tie weekend ahead.

i wanna trade a tm kenwood 261 a two meter mobile
new only 2 months old still have bill and in miint condition reason
for selling i want a digital camera i wanna trade for a digital
camera. any one interested. in trading. i have pictures of the radio
if your interested it got 5 25 50 watts both newmeric and alpha
newmeric readout dial pad mike. and many features auto dial
stores up to sixty channels stores up to 20 phone numbers i thinks.
has many options i can list them all. but realy nice radio. i use it
as a base so never bounced around in car. never hooked up in car.
if interested eamil me i need a digital camera for my comepuer. please
respond with offers.

> I was under the impression that some fluorescence didn't
> involve metastable states. I was thinking in terms of

The process must be time reversal invariant. Excitation
directly to a state which may decay by the same process
must BE the same process. The only way to achieve a long lived
state is to poplulate a state in such a way that the decay
process is inhibited by selection rules. If you

> an atom with a narrow absorbtion band having a small
> probability of absorbing a photon (which would lead to

If you want to think of it in terms of a resonance widths,
you can do that. In fact, it's quite common to do so.
In terms of the reaction cross section, you get the
general Breut-Wigner form,
\sigma \propto [(E - Er) + {\Gamma^{2}\over 4}]^{-1}
for a lot of seemingly unrelated phenomena where E is the
Energy you have to use, Er is the energy required for the
reaction and \Gamma is 1/t, with t = lifetime of the state.
Notice at the energy where E = Er, the probability is a
maximum AND that it says nothing about whether that is
the probability of forming the state or decaying through the
same channel.

This should look uncannily like the impedance of an antenna
which will produce a current for any given potential difference
with some sort of dependence that goes as:
1/[(wL - 1/wc)^2 + R^{2})]

With the exact form being dependent upon all of the relevant
R,L,Cs, but the point being, at resonance, by definition,
the wL cancel the 1/wC. The basic differences between two
antennas that present comparable cross-sections is in the
exact form of the impedance. For comparable wavelengths, your
"energy sucking" is just the antenna presenting the best
current flow due to the impedance and potentials created by
the incoming photons. It's obviously highly frequency dependent.

> a long "pumping up" time) and a small probability of
> emitting one (which would give a long decay time once
> the incoming radiation ceased.)

This violates time reversal invariance.

> THERE'S a key point. If my understanding of the "energy
> sucking" mechanism is correct, then because the process
> involves interaction between the incoming EM waves and the
> fields generated by the resonator, it is NOT reversible, and
> the time constant for intercepting energy is shorter than

That involves two violations that no one plans on giving up
without quite a lot of wailing and gnashing of teeth.
QED and time reversal. If one E&M field can affect another
E&M directly, AT ALL, you have to ditch all of modern
physics. The only self-interacting field for which a theory
exists is QCD, and gluons have a range of quite a bit less
than infinity due to this. In fact, the range cant be greater
than a proton radius and it certainly is not going to have
a 1/r^2 dependence by any stretch of the imagination. As for
time reversal, since it is believed that EVERY physical
law is cpt-invariant, your antenna needs to violate cp
to violate t. Given that E&M is a vector interaction and
charge is a good symmetry, it'll be a hard sell. The weak
interaction can get away with this sort of thing since it's
vector - axial vector. E&M cant.

> Slightly separate topic: does a resonant antenna
> receive more energy than a non-resonant antenna of
> similar geometery?

No. It just doesn't lose energy due to the reactance.

> Does the presence of a tank circuit
> actually change the effective area of a loop antenna,

Only in the sense that from a calculational point of view
you may be able to find a particularly simple way to express
the losses that way, but not as the underlying fundamental
process. Recall that reaction cross sections are done analogously
and are expressed in termas of an area (barns, being the usual
units du jour) Certainly a target nucleus doesn't size from it's
point of view or the point of view of the labratory when the incident
beam enery changes.

> yes or no? In other words, is there evidence that SOMETHING
> occurs, even if it might not be exactly what I am discussing?
>
Take the "energy suck" factor, subtract it from the world
and call the result "power loss due to impedance". Mumble
something about gauge freedom and if it's useful to calculate
an answer, make the connection rigorous, but don't mistake
it for the underlyung physics.

> If you insist that "energy sucking" cannot exist on
> theoretical grounds, but if an ACTUAL ANTENNA does receive
> significantly more energy when it's part of a resonant
> circuit, then experiment beats theory.

>
Experimeents beat theory when they disagree on what the theory
claims the measurements should be and what the experiments say
they are. Your suggested experiment doesn't prove anything other
than the antenna receives more energy connected to a resonant
circuit. It's purely a phenomenological model that may be useful,
like the liquid drop model in nuclear physics, but it doesn't
address "why" at all. For that, you need to be able to predict
a result you can measure that cannot be compatible with any other
model. I don't see any incompatibility with your antenna and
classical E&M and right off hand, I have a hard time imagining
how you could find something that would provide an opportunity
to show a discrepancy.

> topic, then I would be far less confident about the
> existence of the phenomenon.
>
Look, it's possible to take anything and fit it to a particularly
convenient choice of parameters, especially if you have a lot of
parameters (I suggest a brief perusal of the nuclear optical
model which allows the fitting of scattering data to 11 parameters
- which are even physically reasonable after a looking closely).
Given a theory with enough parameters, I can explain the universe.
The hard part is reducing the set to the minimum, not conjuring up
new ones to replace looking deeper into the problem. Anyone
can do that.

> remove the short and see if it ramps up over many cycles.)
> Hey, I can even throw a capacitance across it afterwards,
> to detune it so it ramps back down again.
>

You realize that your Q is defined by the energy stored in a cycle
right? As the impedance has a direct bearing on this, you are
shooting yourself in the foot.

Just for fun, you might want to take a look at Analog Devices "Othello" - it
was featured in this month's edition of Analog Dialogue.

Hi It CAN be doen but it is a lot easier with a SA . Try a RX and a siggen
and tune for max rejection. If you must use a power meter tune for a sharp
null not a peak.
Cheers de Alan G3NYK

Catalog does not have pin out info, but voltages are as follows

input 105,115,210,220,230 volts 50/60Hz

output 580-530-300-0-300-530-580 volts

current 420ma with fullwave rectified and center tap common
290ma with fullwave rectified

INFO from 1970 UTC transformer catalog. 73 Tom WB6IQD

> low cost recommendations for 6m duplexer, anyone, anyone ??

You have 3 options:

1) find used duplexers (big!) they are around from PD's & FD's
moving from low band to high/trunked. They range from free,
to expensive, and might be hard to find.

2) Use split site, and send traffic via linked radios (UHF).
This is very practical & works well, if you have 2 sites.

3) Use large size (1-1/2 to 2") heliax, and make notch stubs
for each line and notch out the other freq. This does work,
a bit less efficient than #2 above, but can be made to work.
You'll need to make about 3 to 4 to make it work right.

Good luck.

In sci.physics.electromag, Richard Herring writes:
>
>Photon-photon interactions are a second-order effect in QED.
>
In QED this is called a 4th order effect. Photon-photon
interaction requires a fermion loop with 4 photons attached,
hence 4 vertices and the 4th power of the coupling constant, e.

>not any innate property of photons. In free space, superposition
>still holds (apart from that 2nd-order QED caveat.)

Breaking of superposition in free space not only comes from
photon-photon interaction, but also the vacuum polarization
(a kind of photon-vacuum interaction). It is important for
the hyperfine structure in every atom. It occurs at high
fieldstrengths (e.g. 10^21 V/m, or 10^12 Tesla).

And if you compute the fieldstrength at the outside of one
single proton (radius about 10^(-15) meter) you find ... !

That's not called a log-periodic antenna, but a Yagi-Uda antenna
because it was invented by Mr. Uda.

(Mr. Yagi presented it outside Japan and explicitely attributed it
to his colleague, but probably the attendants did not listen, or
could not understand his English).

>third 612 as a 445 Khz mixer for SSB.
>
Hi
I really don't see the point in convertion to 455kHz for AM and SSB,
it might be a point 40 years ago, as would it be to go further to
50kHz, but the only argument to use 455kHz is to demodulate NBFM

on the other hand you could go from 10.7 to 50kHz for DSP, but if it
is just conventional arrangement you wish to have it is easy to find
suitable AM and SSB filters on 10.7MHz

One suggestion is to use NE614 as a multimode detector for AM SSB FM

This argument is spreading all over the place. I want to
focus on one little part before going any further.

Please help me understand your position: are you saying
that, at resonance, if the short antenna's (real, lossy)
tank circuit appears as a nonreactive resistance, and
then if I replace the whole tank circuit with a carbon
resistor of the same value, the SAME energy will be received?

Just so there's no misunderstanding: place a load resistor
across a very short receiver-dipole and ADJUST THE
RESISTANCE for maximum received power. Measure the power
in the resistor somehow. No tank circuit. (Assume it
is receiving a CW radio signal.)

OK, now place a lossless LC circuit across the resistor on
the above dipole antenna, tune it to resonance, and
re-adjust the load resistor for maximum received power
(is this even necessary?) In both cases the short dipole
sees only a resistive load attached to it. In both cases
that load has been adjusted for maximum received power.

Will the received power being dissipated by the load
resistor be the same in both cases?

Hi,

I got a lot of these - about 75 - 80 I think. They have a B7G socket
and is about the same size as a 6AQ5 valve. All metal. Yellow colour.
The label says:
IF AMPLIFIER AM-427 A/U
FISHER RADIO CORPORATION
U.S.

Inside this hermetically sealed box there is a complete IF-amp. One
5678 subminiature valve, two inductors a few capacitors and resistors.

They are all new and in original boxes. I really don't need them
myself, but maybe there is anyone out there who do?
E-mail me if interested I can send a pic.

Regards,

Arnold Goksyr

My point is, antennas don't "suck", (well, some probably do, but not
in the context given here). I was attempting to use your descriptions
to point out what's happening, since you want to view it that way.

> tank circuit appears as a nonreactive resistance, and
> then if I replace the whole tank circuit with a carbon
> resistor of the same value, the SAME energy will be received?
>
Depend upon how you define "receive". As in you have an equal
opportunity to make use of it? None is re-radiated? what?
The same number of photons strike the antenna. Your ability
to make use of them varies.

> Just so there's no misunderstanding: place a load resistor

j

Impedance diagram: +------------> R

Z=R

That's not true. The dipole itself has some reactance, especially
a short one. Adding the tank circuit and tuning it for resonance

removes that reactance from the circuit. Tune your tank circuit
WITHOUT connecting it, then connect it and don't change the
resistor and see what happens.

> that load has been adjusted for maximum received power.

In one case yo have R + X_ant

in the other you have R since tuning the tank circuit
accomplishes X_tank - X_ant = 0 by definition of resonance.

The 485 has a switch mode PSU in it. It is under the metal cover in the rear. Check the TO3 transistors they are plugged in come out easily. I had one of the two 470Mfd. go open circuit on mine, they are under the power board but you can check them via the fixing screws from the board top to see if there is capacity. The ticking sound is the PSU turning on for 20mS. say Oh hell! and turning off. The smart part of the scope is probably still fine. Don't panic and check the above points. Feel free to e-mail me again.
Robin PS Don't kill yourself on the PSU!! I rectifies the AC to 350V.

Received power dissipated in the load resistor attached to
the antenna.

> The same number of photons strike the antenna. Your ability
> to make use of them varies.

If by "strike the antenna" you mean "come within a
quarter-wavelength distance", then we all agree. The
absorbtion occurs across the nearfield region. A small
resonant antenna absorbs a far larger number of photons
from its nearfield region, and a non-resonant antenna
absorbs far fewer. If the Poynting vector fields of a
resonant and non-resonant antenna are plotted, then in
the former case the vectors in the nearfield region curve
inwards to strike the tiny antenna, and in the latter case
they go straight by as if the tiny antenna was not there.
(This is not my stuff, this is straight from the two
physics papers.)

BINGO! There it is. In your language, I should be saying
"cancelling the built-in reactance of a small antenna
causes the received power (in the load resistor!) to go up."

If you wish to call it "cancelling the reactance", while I
call it by a different name, then we're discussing the same
thing. (If my EXPLANATION is wrong, that's different.)

If I insist that phenomenon involves the phase of the
time-domain changes in the shape of the fields
surrounding the antenna, and you insist that it involves
the antenna's reactance, then we are essentially talking
about the same thing, since the capacitance of a small
dipole (or the inductance of a small loop) as a concept
cannot be divorced from time domain and the shape of the
fields. Looking at measured capacitance and looking at
how geometry shapes the fields are two different ways
of looking at the same thing.

But rather than speaking in terms of reactance, I want
to analyze this circuit in terms of the current and voltage
of the antenna moment by moment, and the b and e-fields
which the current and voltage create. I want to ignore
the concepts "capacitance" and "inductance", and instead
watch the flux change over time, and look at the 3D
structure of the Poynting-vector field. Why?

As Feynman said (paraphrased), "unless you have four or
five ways of looking at something, you don't understand it."

Or Alfred Jarre' once said: "why, to be weird!"

But seriously, I see that observing the time-domain fields
gives insights that normally remain hidden within
"capacitance" and "inductance" concepts as applied to
antennas. The time-domain field changes give a viewpoint
that static reactance concepts do not.

Whether other parts of my aloud-thinking are flawed is
a separate issue (which I will continue to pursue.)

As for "sucking", I don't think there's any question that
the addition of a resonator bends the Poynting vector
energy flow inwards. If you think "sucking" is a bad
description for this, it has nothing to do with whether
cancelling the reactance causes the energy-flow to bend
inwards or not.

Also, please note that I described "energy sucking" in
these terms in the exchanges which started this entire
thread:

http://www.amasci.com/tesla/tesceive.html

Adding an inductor to a simple "capacitive antenna"
causes the AC voltage on the antenna and the received power
to both rise significantly. My example didn't involve
propagating waves though.

I would avoid the Millens unless you are using them between modules in an enclosed, interlocked cabinet. They are unsafe otherwise as when disconnected they permit easy contact with the terminals.

For safety's sake, you want a connector that has two poles: HV and return. Otherwise if you connect the high voltage to a piece of equipment that is otherwise ungrounded, its chassis could reach deadly potentials.

SHV are very good. They're OK to around 5 kV if I recall. They're not cheap, but we're talking safety here. A few tens of bucks is worth it.

MHV are less good, I'm told. First, the HV makes before the ground. Second, I've heard you can contact the HV by connecting a BNC to them.

For higher voltages, I've heard the connector sets by Alden products are good but have no experience with them.

Some may pooh-pooh the safety aspects, saying "Well, I'll never open the connector when the HV is on." My answer: The probability of a fatal event should be very low. That probability is equal to the probability of me doing something stupid times the probability of death given that I did something stupid. Using the right connector dramatically reduces the second factor.

Michael,

I have a couple of old but serviceable bits of hardware that I rebuild the packs for. Most battery packs are ultrasonically welded. The seams will give it up if you freeze the pack for a few hours and then tap the seams with a small ball-peen hammer. Don't whack it, tap it. When the case is open, scope out the cells and replace them with new, tabbed cells. Replace them all at the same time, this isn't the time to cheap out! Look into getting newer, higher capacity cells. You can get 800mAh AA cells that are the same size as the 600mAh ones. Re-assemble the pack and use a little Plasti-Zap (cyano-acrylate for plastic), available from your local hobby shop) to cement the case back together. Do a nice, slow overnight charge and enjoy your handiwork.

Forget the 1/4 wave bit for the moment. Just think of putting.

A golf ball rolling over the hole falls in. One rolling around
the edge that doesnt fall in, still interacts with hole, the
hole doesnt conspire with the sandtrap to cause the ball to
miss the green (but since I dont do golf, ...)

This is hardly a novel concept. Any antenna has some reactance
associated with it. Take a piece of wire with a self-inductance
"L". Put it high enough above the ground and far enough away
from other conductors to neglect the capitance. You have an antenna
with a resistance R and inductive impedance jwL (taken to be in
parallel) for a net impedence of:

Z = [1/R + 1/jwL]^{-1}

|Z| = wLR/[R^2 + (wL)^2]^{1/2}

For a potential V that develops between the endpoints,
V
I = --- [(wL)^2 + R^2]^{1/2}
wLR

Power dissapated in a resistive load (consider the R in the
antenna the load: For practical purposes, it is) :

P = IV cos(\phi) ; \phi = atan(-R/wL)

Note that (1) adding a capacitor changes I AND the power dissipation
on each cycle. At resonance, the current flow is simply
V/R and \phi = 0.

BUT wait... There is more. The atmosphere (or free space) has
a characterisic impedance, so you have the further constraint
that at the resonsnt frequency the impedance should match the
medium surrounding it. For the same reason you put terminators
on coax - impedance mathing.

> If you wish to call it "cancelling the reactance", while I
> call it by a different name, then we're discussing the same
> thing. (If my EXPLANATION is wrong, that's different.)

Well, I hadn't considered reinvention of impedance matching to
be where you were trying to go here.

> If I insist that phenomenon involves the phase of the
> time-domain changes in the shape of the fields
> surrounding the antenna, and you insist that it involves
> the antenna's reactance, then we are essentially talking
> about the same thing, since the capacitance of a small

No. We aren't. Impedence matching occurs RIGHT at the BOUNDARY
and those BOUNDARY conditions are responsible for the fields.
Your viewpoint reverses cause and effect. Your boundary conditions
are fixed by the properties of the materials and the geometry
to produce fields consistent with those conditions -unless you
plan on allowing the antenna to move around on its own and
alter its atomic composition to "seek an optimal field shape".

> But rather than speaking in terms of reactance, I want
> to analyze this circuit in terms of the current and voltage
> of the antenna moment by moment, and the b and e-fields
> which the current and voltage create. I want to ignore

The fields don't determine the reactance. For example,
capacitance is a purely geometric property for a
given configuration of conductors. It matters none whatsoever
that you put 10 coulombs on two 1x1 plates psaced 1 in or
you put zero coulombs on them (apart from needing an army
of lou ferrignos to hold the plates in place). The capacitance
doesnt change.

It's not strictly true, because a high frequencies, the
effective geometry changes due to the skin effect and you
cant consider anything but the geometry of the surface
as you go up in f. (I cant see that it affects a capacitor
to any real extent, but an inductor, it will).

> the concepts "capacitance" and "inductance", and instead
> watch the flux change over time, and look at the 3D
> structure of the Poynting-vector field. Why?
>

Yes, why? The Fluxes are determined by those things:

\phi = LI, inductive

Q = CV ==> di/dt = C dV/dt + V dC/dt
/
[N.B. the last term is called a microphone]

> As Feynman said (paraphrased), "unless you have four or
> five ways of looking at something, you don't understand it."
>

Yes, that's always a good idea, but he probably didn't
mean "try and convince nature to adopt a new strategy"

> Or Alfred Jarre' once said: "why, to be weird!"

Yeah. Those would be what would be more natural to
consider in a quantum picture that treats photons
not waves, uncertainties in postion on the antenna
not wavelengths and boundary values. For that, draw a
box of size X x Y and calculate how it should be shaped
to cover the largest surfaace area under the constraint
that no part of it extend past the point that a photons
leaving the broadcast antenna that correspond to
the smallest time difference over which the signal
may change, not overlap due to the uncertainty in
their emission times. There's a standard dipole
in there.

Among other things, sucking tends to imply some action on the part of the sucker to create the suck which sucks in the suckee.

Hello Michael

Saft is the battery Manufacturer, Radio Shack has replacement batteries and I think they are also by Saft. RS has Ni-cad's with solder tabs, I buy two of their 3-packs and tape them togother in the same arrangement of the original Saft 6-pack. It only requires one jumper to connect the 3-packs, then connect the four wires as they were to the original. I have rebuilt several and they work fine. As the other gentlemen pointed out it would be nice to use 800ma, the RS replacements are 600 or 650ma units. I believe I paid less than $20 out the door for two of the 3-packs.

Hope this helps, KF6HHS

I'm planning to build amplifier with one or two 833 tubes.
There might be problems with hi HF bands due to
large physical dimensions of tube. Stray capasitances may
too be high.
Does anyone have experience with 833 ?
Any articles in old magazines or handbooks ?

answers to group or jyrkituo@iobox.com please.

1861. Re: help please, i want to tune a duplexer with common tools =]

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-10 00:00:00 UTC

I started out to echo the group sentiment of "forget it".
But while explaining why it can't be done, I came across a
possible soultion. I've never tried it, it's just
speculation
at this point.

A spectrum analyzer has several things going for it. You
can see
the whole curve, so you can easily set the split. If your
duplexer
has a fixed split, or correctly adjusted split, you don't
need this.

The dynamic range is much larger than you can get from a
simple wattmeter,
although wide range wattmeters exist.

The major advantage of the spectrun analyzer is super
shielding.
You're (mostly) measuring what comes thru the input
connector.

A communications receiver has very wide dynamic range. But
it lacks the
shielding to make the measurement.

So, what if we borrow a technique from bunny hunters. Build
a small box
with a mixer and battery powered oscillator inside. Shield
the bejesus out
of the box. Tune your receiver to the desired frequency
plus or minus the offset.
Now you're measuring what comes in the mixer input connector
(mostly).

You may well be able to tune the notches for a null. This
will be frowned
on by the purists, but may well be a workable solution for
the spectrum
analyzer challenged among us.

Remember, this only works if your duplexer is already the
right split
and is working properly. You won't be able to see funnies on
the attenuation

curve.

So, what do you think about that?

here's a link to a homebrew 6m duplexer page

I wonder if anyone can point me to any Internet sites describing a top band solid state pll AM tx.

I have several pll designs but unsure of which type of modulator to go for.

I'd like to keep things as simple as possible and try and find a way around the need for any modulation transformers.

Any help appreciated.

I stand corrected. The point's the same, though. It's not significant
under the conditions discussed here.

Use a low level modulator. Hard drive the base (class C) of a BC109
from the carrier generator . There is a tuned circuit in the collector
damped down to a Q of about 8. The DC supply to the modulator is low,
say 1/4 of the transmitter's DC supply.

Use another BC109 as an emitter follower to 100 percent audio modulate
the DC supply to the modulator..

Follow with a linear class-A or class-B RF power amplifier driven via
a tap or a link winding on the aforesaid tuned circuit.

* * * * * *
Why do you want a phase-locked-loop on 160m AM. A VFO at carrier
frequency can be made stable enough. If you are not happy with that
then make a VFO which covers, say, 500 to 700 KHz and beat that
against a crystal oscillating at 2500 Khz.

A trifilar winding is simply a winding made of three wires bundled together.
The dot can be thought of as the beginning of the winding, and when you
start winding the three wires all the dots are on the same end.

Thus the dots are all in phase and are of equal value.

That is, if I understand your post.

I found this during a google search. I read "indicates the presence in free space of a novel, longitudinal, magnetic flux density" and after having read something somewhere in the past about circularly polarized lasers being attractive or repulsive, I ASSUMED the photon actualy has a magnetic moment.

Scott

"THE PHOTOMAGNETON AND QUANTUM FIELD THEORY
Volume 1 of Quantum Chemistry

by A A Hasanein (King Saud Univ. & Univ. Alexandria) & M W Evans (Univ. North Carolina)

This first volume of this two-volume set deals with the important recent discovery of the photomagneton of electromagnetic radiation, a discovery which is fundamental in quantum field theory and in quantum mechanics in matter. The photomagneton is the elementary quantum of magnetic flux density carried by the individual photon in free space, and is generated directly by the intrinsic angular momentum of the free photon. The volume develops the theory of the photomagneton in a series of papers, which cover all the major aspects of the theory, from classical electrodynamics to the relativistic quantum field. Several suggestions are given for experimental tests, and the available experimental evidence is discussed in detail. The overall conclusion of the series of papers is that the photomagneton, which is observable experimentally in magneto-optical phenomena, indicates the presence in free space of a novel, longitudinal, magnetic flux density, linked ineluctably to the usual transverse components. If the photomagneton is not observed, then a paradox would have emerged at the most fundamental electrodynamical level, necessitating a modification of the Maxwell equations themselves. "

Not stated is what type of duplexer we're talking about here. Is it a band pass only, band reject only, or a combination? It's fairly simple to set the bandpass using a signal generator and receiver with attenuator. Alternatively, a low power HT can be used as a generator in conjunction with a low wattage reading wattmeter.

Most duplexers are designed to handle 50 watts or more but if one wants to exercise caution while tuning, the tuning can be done in power on - measurement - power off - tune - power on - measurement steps to 'walk' the bandpass adjustment to the correct neighborhood. This being done with the low power HT/wattmeter combo of course.

Tuning for the notch frequencies can be done with a signal generator - receiver combo. If the receiver has a limiter meter reading, that's helpful. Otherwise one could inject a tone with the signal generator and either use ear or a scope while adjusting for minumum signal on the notch frequencies.

I agree that a specturm analyzer is very useful with setting up a duplexer, but simpler equipment can be used as well...indeed, this is what was done in earlier times.

What *local* electromagnetic field would that be? And how does
it "grab" another field? What is the source of its energy?

IMHO there's only one electromagnetic field, the one generated
by the emitter. All of the EM effects we are discussing are a result
of this single field. The energy for this field comes from the emission
source. There is no other energy source to produce other fields.

Yes, I object to that. You're creating out of whole cloth
some mysterious unpowered EM field that doesn't exist,
which you say "grabs" other EM fields when they superpose
(at some distances but not at others). That simply sounds
like nonsense.

> I think you might want to review your concepts, since
> the idea that "fields allow antennas to intercept EM

Fields are what receiving antennas intercept. Those
fields are generated by other antennas being driven
by energy sources.

>> The energy has *not* "gone missing".
[due to superposition of fields]
>
> Gone missing FROM SPACE, from the travelling EM wave. The

> true of a tiny resonant antenna.

No, that's not the context. Two EM waves crossing in space do not
lose any of their energy, either to each other or in any other fashion,
due to superposition. Superposition never alters the components
of the superposition in any manner. This is the fundamental principle
upon which all superposition is based. If you reject this idea, then
you are rejecting the entire basis of (classical) wave mechanics.

(When a charge is accelerated or decelerated, and only
then, is electromagnetic energy produced or absorbed.
There are no other methods.)

>> That is a misunderstanding of what has happened.

> realized this was unconventional, but people here are
> attacking some concepts which I didn't think were
> controversial or even open to debate.

The concepts are totally bizarre, and have no physical
basis. There is no "local field" unless you have a transmitter
hooked to the receiving antenna (in which case that simply
overloads the receiver and you extract no useful signal at
all from the distant source). There is only the field from
the distant transmitting antenna, which is arriving at the
receiving antenna where it accelerates charges on that
antenna. That acceleration of charge is an AC current,
which can then be modeled by normal circuit theory.

> If you are certain that a normal half-wave dipole can
> intercept EM waves without the dipole generating fields

> have a serious problem. You're no longer arguing about
> the tiny antennas, but instead have begun questioning
> antenna-physics itself.

I'm certainly questioning your notion of antenna physics.
It is true that any receiving antenna will reradiate a portion
of the energy it receives from an EM wave that it intercepts.
But reradiation is an EFFECT, and not a CAUSE. You're
putting the cart before the horse.

There is no local EM field until the antenna is excited by the distant
EM field. That's because there's no energy source to accelerate
charge until energy has been obtained from the distant field.
This reradiation is what happens to some of the energy coming
from the distant source *after* it encounters the antenna. It is not
there a priori to "grab" that incoming wave. It doesn't hang around
to grab later waves either. It simply radiates off into space, never
to be seen again.

Look, we can simplify this situation to its fundamentals and
derive any other more complicated case by use of superposition.
The fundamental case is to have two point charges separated in
space. One over here, another over there. If you wiggle the one over
there, the one over here wiggles in sympathy. Action at a distance.

Momentum has been transferred across empty space. We need some
mechanism by which momentum could be transferred from over there
to over here. Experiment showed that there was a lag between wiggling

the charge over there and when the charge over here started to wiggle.
That lag was proportional to 1/c. Momentum transfer and finite velocity
of transfer hint at the presence of a particle, which we call a photon.

Now the photon has no rest mass, but it does have size of a sort. Its size is
inversely proportional to the energy one quantum (photon) carries (E=hv).
As frequency v increases, the "size" of the photon decreases. (This explains
several things about antenna behavior at different frequencies.) Due to wave
particle duality, this size is what we can call the wavelength of the photon.
(We can map this extended particle out as a field, but that is only a mapping.
I'll stick to picturing particles of differing sizes here.)

A quantum is indivisible. Either all of its energy is transferred, or none of
it is. When any part of a photon intercepts a charged particle, all of its
energy is transferred to that particle, or none of it is. No fractions allowed.
(This is fundamental, and fundamentally different from the classical view.)
Small antenna or large, it doesn't matter. As long as it intercepts any
part of the photon, it intercepts all of it. No local "sucking" fields are
required to explain why a small antenna (in terms of wavelength) can
receive nearly as much energy as a large one. (What the antenna can
usefully do with that energy is another matter, involving circuit theory.
Since the small antenna will be highly reactive, efficiently extracting
the energy it has intercepted to do useful work will be difficult.)

We can explain this another way. We can say that the presence of
the receiving antenna alters the permeability and permitivity of the
space in which it resides. The field mapping of the signal originating
from the distant source changes from what it would be in flat empty
space, and the field lines concentrate around the antenna. The result
is the same, just the point of view (wave or particle) is altered. In no
case do we need "sucking" fields to exist. (Good thing too, since
there is no such thing.)

The key concepts are that a quantum is all or nothing, and a quantum
has an effective size inversely proportional to its energy (and frequency).
If any part of it brushes a charged particle, all or none of its energy will be
transferred to the charged particle. It takes direct interaction with charged
matter to alter a photon.

1880. Advise on insulating wire for high voltage power supply

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-10 00:00:00 UTC
From: "William J. Erwin(Bill)" <werwin@columbus.rr.com>
Message-ID: <Atey4.25369$h.158205@typhoon.columbus.rr.com>
Source record: 62685

I am looking for advise on adding additional insulation to std. wire that has an outer covering rated at 600 - 800 volts. I am building a power supply that has an unloaded voltage of around 3KV. Is it safe to use flexible plastic tubing to increase the working voltage of the existing low voltage outer covering?

Thanks in advance,
Bill

From what I can tell, that isn't the implication, The field from
something with a magnetic moment is carried by a photon. This field
is carried by a particle designated B(3). Also, one should view with
caution anything that mentions ghost-fields. Do you have any other
references that have some better info? It's kind of interesting.

>dr.d

no, 614 or 604 - see G8IBR's circuit mentioned in text below.
or you can of course use MC1351, MC1357, TBA120/SN76660N or other

see NE614 data, FM application is shown in Fig 4, AM detector is shown
in fig.7
The simplest application of using NE604/614 as multimode detector is
to use the first IF amplifier (pin 16 to 14) for all modes, after the
filter use a switch (1) connector filter output to pin 12 (FM/AM), and
(2) to to break connection between filter and pin 12 for SSB and
connect BFO signal to pin 12 (suppose 50mV is works).
Another line goes between filter output to another switch - pt.A

this switch selects between 'A' connected to pin 8 (fig.7) for SSB/AM,
or quadrature filter (including 10pf from pin 9) connected to pin 8
(product detector)

RSSI function is lossed for SSB since the limiting IF amplifier has
constant signal from beatosc.

Scanned and sent you the G8IBR circuit from Radcom 12/76, this uses
MC1351P as multimode detector on 455kHz. Understanding this circuit it
is quite easy to decide how to connect NE614. I've made a sketch how I
would connect NE614, but the problem is to decide which switch
elements will works with satisfactory cross-talk, so perhaps easier to
use 455kHz or lower IF.

I used TBA120/SN76660N in AM/SSB demodulator, also use MC1351 as AM
syncronous detector in a BC receiver to avoid problems with selective
fading and improve sensitivity (S/N on low signal strength). TBA120 is
very much like SL624 (SL1624?) multimode detector, but somewhat
unlinear product detector. It was found useful for several other
applications for 1kHz to 15MHz, the limiting amplifier may also work
as oscillator, wien-bridge oscillator for the lowest frequencies and
xtal (or ceramic element) oscillator for the higher

Automotive ignition wire is ideal for that application if you have room for the thick insulation, usually about 8mm. It's available at automobile parts stores. You want the regular conductor type, not the suppresser core.

Uh. Are you imagining that the effective area of an antenna
is the physical cross-section of the wire, viewed broadside?
I mean, do you imagine that RF photons come flying in on
straight trajectories, and if they miss the wire by a tiny
bit, they go right on by? That's what you seem to be saying
with your golfcourse hole analogy. If so, then you are flat
out wrong. The whole point of the Bohren paper is to explain
how a resonating particle can absorb TOO MUCH energy. Somehow
it's able to grab EM energy which was flowing by at many
particle-diameters distance. In your analogy, if the particle
is a hole in a golfcourse, then something mysterious is
occurring, because that tiny hole is intercepting golf
balls which never even rolled onto the green.
Without resonance, Bohren's particles behave as your
"golfcourse hole" analogy. If resonance plays a part,
suddenly the size of the "hole" is greatly increased,
and increased to far larger size than the physical
particle diameter. How can this occur?

If I double the diameter of the wire in a conventional
1/2-wave dipole, would you predict that the received

power must double? That's what your "golfcourse hole"
analogy implies.

> > BINGO! There it is. In your language, I should be saying

> > causes the received power (in the load resistor!) to go up."
> >
> >
>
> This is hardly a novel concept. Any antenna has some reactance
> associated with it.

Then why are physicists writing papers about it? The whole
point of those papers is to explain how small particles
are able to absorb EM energy as if their diameters were
far greater than their physical diameters.

"How can a particle absorb more than the radiation
incident upon it?" If the particle is like a hole in
a golf course, then how can it grab any more than the
photons which actually hit the "hole"? But they do! I
think you don't understand the reason for those papers.

It's to explain known experimental results.

Do you have an explanation for how a tiny metal particle
can intercept EM radiation which is a large number of
particle-diameters away from its surface? The phenomenon
only occurs at resonant frequencies. How do you imagine
the particles are able to do this? Why does it only
occur at resonance?

> > As for "sucking", I don't think there's any question that

> >
>
> Among other things, sucking tends to imply some action on the
> part of the sucker to create the suck which sucks in the
> suckee.

Add a resonator, increase the effective area of an
antenna. Increase it so much that the effective area
has a diameter MANY TIMES greater than the length of
the antenna. The antenna is interacting with photons
which SHOULD BE COMPLETELY MISSING IT. This sounds like
"sucking" to me. Or "lensing". Or "poynting-vector
deflecting." Or whatever you want to call it.

Perhaps you are imagining that the resonator only lets
the antenna absorb a bit more of the energy that passes
within one antenna-length distance. If that's all that
it did, I wouldn't be the least bit excited, and those
physics papers would never have been written. The resonator
lets the antenna absorb energy which can miss it by
thousands of antenna-lengths (in the case when the
physical antenna is thousands of times smaller than
1/4 wavelength.)

Yep. It only works for short antennas. And how can it
simultaneously absorb and generate a complementary field?
Not be being reactive per se, but by having a memory.
By storing energy from previous cycles, then using that
energy to drive an oscillator connected to the same
antenna, which absorbs MORE energy for future cycles.
Which is what a tuned circuit does naturally. It can only
work if the phase of the incoming signal is not varying
all over the place. Which is the same as saying that
it works best for single-frequency waves and high-Q
resonators.

Thats what it SEEMS like, until you find out that the
antenna is absorbing energy which would otherwise pass
by at a large distance. "Load matching" implies that
we're letting the antenna grab energy which was already
there. The suprise: "already there" includes
the whole nearfield, and if frequency is low and the
nearfield region is huge, then the antenna acts like
it is "reaching out" across a non-trivial area.
Call it "load matching" to hide the details, or "energy
sucking" if you like controversy! :)

>
> It might be easier to understand with a series L
> rather than a shunt L. I think this is the same
> concept as base loading the antenna.

Could be. Is a base-loaded antenna only effective over
a certain frequency range? I thought that base-loading
was some sort of impedance matching, but if it forms
a low-Q resonator, then it might be analogous to putting
a capacitor across the loopstick in an AM receiver. For
longwave using electrically short whips, it's gotta be
a good thing.

Yep. Active drive can't grab any more energy than a
passive resonator, and it dissipates energy in the
load resistance. It just allowed them to make the
"energy-enhancement effect" be broadband, since they
weren't relying on a resonator to supply the "drive field."
In the frequencies they were messing with, it let them see
fast-changing signals which otherwise could only be
detected with long integration times, which normally
blocks observations of fast-changing signals.

I wonder if "energy sucking" applies to acoustics? If I
connect a resonant chamber to an orfice where the orfice
diameter is far smaller than the wavelength, will extra
energy pass through that orfice?

> some study, but I don't tend to think of that depression as
> sucking water out of the tub and shoving it down the drain.

Say I have one electron. It is surrounded by a
radial e-field. A distant proton is surrounded by a
similar field. Hold them close, and the "two fields"
superpose to create "one field" with a dipole pattern.
The radial fields have apparently vanished into the

dipole field. However, if I move the electron around
without moving the proton, the result will be as if I
had moved the electron's underlying e-field, as if the
"two fields" were still there inside the "one field."
OR I could imagine that the charge on the moved
electron had merely distorted the "one field." Which
viewpoint is right?

Does the current in the antenna simply distort the one
EM field? Or does the independant field generated by
the antenna-current superpose with the UN-distorted
EM waves in such a way as to deflect their trajectory?
Either the charges cause the EM waves to deflect inwards,
or the "antenna's local field" does the job. It's
two ways of looking at the same situation.

In years of arguing with people, I find a spectrum of
philosophies with two opposite ends: on one end are
people who know the world is REAL, and therefore there
must be ONE explanation for a phenomenon. Any other
explanations are therefore distortions, or perhaps
blasphemy, but in any case it must be stamped out or
at least prevented from contaminating the One True
Explanation. At the other end of the spectrum are people
like Feynman, who realize that we can only see the world
through our mental models, but never perceive it directly.
There is not one "right answer", there are a variety.
The more mental models one has in the "toolkit", the
better one understands reality.

> currents and the H component is attributed to the
> load current. And it works fine.

Yes. My version from long ago: drive your
electrically-small toroid with RF, but it cannot
radiate since it's too small and it lacks an external

b-field. Now thread the toroid with a straight rod
which is 1/2-wavelength long. The metal rod has "let
out radio waves!" They were blocked by the lack of a
b-field. If we were dealing with megawatts of UHF
with superconducting coils, it could be dangerous to
poke a metal rod into an apparantly-intert tiny ring.
Suddenly your corneas would fry and your fillings would
melt.

A free running VFO should be stable enough for AM. Alternatively use a
1834 KHz crystal - these were used in XT computers for ?video card

If you want a high level mdulator you could use a switch mode FET as
the power amp (class D efficiency should be up around 90%) and a
switch mode power supply with the audio varying the duty cycle of the
PSU (pulse width modullation). You obviously need a filter after this
to get rid of the switch mode subcarrier (say around 100KHz)

Another possible scheme I have seen uses logic inverters as an
oscillator with a cystal. Following the oscillator is an RC integrator
circuit which converts a square wave from the oscillator to a
triangle wave which is then DC summed with the audio signal. This
combination is applied to another logic inverter - the effect is again
to produce a PWM signal. Again this can be amplified in a class D
system, though I am not sure of the spectral purity.

If you wanted to get really fancy you could use the new DDS chip from
Analog Devices (AD9853) which can be amplitude modulated with a
digital signal though this would be quite involved.

I would be interested to know if anyone has actually done any of this

The Regular ignition wire for a long time has been what would be unuseable to this person.....I know what you fellows mean, and further add that he'll have to seek out copper core (not Steel either) ignition wire for his purpose. Another type of wiring might be to use HV test lead wire (obviously have to see if the gauge to handle the current is available)...Belden would be one maker (might have to buy a small roll however).

If you literaly suck with a Hoover, sound will be refracted into the orifice
:-)
You can put disk resonators in an array to form an acoustic antenna (looks
like a lens), but its not too efficient
Reflectors work better.

I prefer to condsider the space occupied by the particles is capable of
being polarized, or polarizing virtual transient electron/positron pairs, or
affecting potentials, or whatever, due to the character of the particle
occupying the space.

> Does the current in the antenna simply distort the one
> EM field?
> Or does the independant field generated by
> the antenna-current superpose with the UN-distorted
> EM waves in such a way as to deflect their trajectory?

I'll reiterate again, An incident wave's field induces currents and voltages
in the antenna, which (antenna resistive loss notwithstanding) the antenna
then re-radiates. If the antenna isn't resonant, there will be a phase
shift, which can be called reactance, that will then bend or refract the
waves. Any old additional signal on the antenna will just superposition. The
wave in question is bent, because it is synchronized with itself.

One mental hangup I, and others I've seen have had, is thinking of space as a place where seperate, individual waves are traveling in all different directions. Space can be thought of as a crystal lattice, where the elements of the crystal at any instant are the sum of the myriad of waves. Actualy space is like a boiling foam, at a small enough level.

Just as a further note....the least amount of insulation available for automotive wiring would be ok for lots of applications as it (older and maybe more likely available copper core) only had to contain systems producting up to 20Kv or so. The 8mm stuff is used both to insulate systems running up to 50Kv AND against extreme heat in todays cramped compartments or in high performance engines. Good ideas though!

> Uh. Are you imagining that the effective area of an antenna
> is the physical cross-section of the wire, viewed broadside?

If P watts are radiated into 4-pi and you cover all 4-pi with n antennas, then what is the average power absorbed by each if all n antennas are equivalent, 100% efficient and lie a distance r from a source which radiates isotropically? If you have an answer different from P/n, stop reading and subscribe Astrology Today, since you've violated conservation of energy. Now assume they are 10% efficient rather than 100%, but all of them have a 10% efficiency and nothing else is different. If you didn't get 0.1 P/n for each, you'll have to come up with some excuse to arrive at an asymmetric answer to a completely symmetric problem. I'll get to the case of identical gaps in a moment, but first, nobody seems to have a problem with this concept when applied to gamma rays and scintillators, why should it differ for an antenna? photons are photons. Just because certain phenomena produce high energy photons (like the peaks in 60Co) and some produce lower energy photons (like a radio), why should there be a difference in the way they behave other than using a detector that takes advantage of phenomena of the appropriate energy scale? (you wont see any scintillation in a NaI(Tl) crystal from channel 4, for example).

> I mean, do you imagine that RF photons come flying in on
> straight trajectories, and if they miss the wire by a tiny
> bit, they go right on by? That's what you seem to be saying

Go draw a probability distribution about some point P(r,\theta, \phi) in space for a photon emitted in the interval of ime t + \delta t from a source at the origin (or the equivalent -- calculating the probability distribution for it being anywhere else) Now trace the center of the probability distribution over the length (or surface area if you don't have approximately a line of some sort for an antenna). Now figure in the phase space factor (the probability of absorption vs some other process, like elastic scattering, inelastic scattering, multiple scattering, etc., due to kinematics). By the way, this same excercise tells can be used to descibe skin depth. The attenuation is nothing more than what you get when considering the penetration of a potential step by a particle wit wavefunction \psi. It just may not be easy to come up with a height, V_o, for the step from first principles.

>
> If I double the diameter of the wire in a conventional

> analogy implies.
>

Do you really want me to finish this? I can, but I imagine it's
getting tedious to read as well as try to find the clearest way
to get the point across. However, I will if there is any point
to doing so and I'm not just wasting my time by providing an
infinite number of possibilities to digress and avoid just having
to deal giving up on the "energy sucking" tack. I'm not about
to deal with an endless series of irrelavent tangents.

As a starting point, you might consider thinking of the antenna
as a large collection of point-like receptors of a phased array
that add up at the point the signal is injected or detected with
the relative phases determined by the distance from that point
and the frequency of the carrier. You'll see that it's not as
obvious that twice as physically large corresponds to twice the
collection efficiency since you are also constrained in time by
the requirement that later signals arriving nearer the collection
point cant overlap earlier ones from further away.

>> This is hardly a novel concept. Any antenna has some reactance
>> associated with it.
>
> Then why are physicists writing papers about it? The whole

Don't say physicists. Say: A. Uthor, Journal of Stuff,
No. N pp# (yyyy)

I cant comment on what is even being claimed without seeing the paper
for the simple reason that if I think you've misinterpereted some
genuine scientific research, I'm not any more likely to think it backs
up your claim. On general principles, (which, if need explaining, means
don't bother to do so) and just the basic waste of time, be sensible
about A. Uthor and Jounral of Stuff. I consider Astrology and the usual
keelynet fare to be equally wasteful examples of points which the
divergence of information is always negative -- no matter what
information goes in all that emerges is the ascii version of blackbody
radiation. Someday, a credible theory of something may ooze out, but
that day isnt today.

>
> "How can a particle absorb more than the radiation
> incident upon it?" If the particle is like a hole in
> a golf course, then how can it grab any more than the
> photons which actually hit the "hole"? But they do! I
> think you don't understand the reason for those papers.

Before you ask me to finish the above, do you understand the concept of probability distributions as opposed to a deterministic case? Do you understand why quantum mechanics allows tunneling through a barrier while classically tunneling cant occur? If not, this wont make sense either.

> It's to explain known experimental results.
>

As I said before, with an infinite number of parameters to cover every phenomenon, the "I have a new theory of everything" or the "Let me speculate without considering the implications" , approach anyone can explain the universe and by increasing the jargon can bullshit people lacking a big enough shovel. Providing the minimal description of nature in a consistent way is the hard part.

> Do you have an explanation for how a tiny metal particle
> can intercept EM radiation which is a large number of
> particle-diameters away from its surface? The phenomenon

It doesnt. It's your notion of "a distance away" that's the problem. Photons are not classical objects. You cant treat them that way. You can only treat their probability density that way.

> Perhaps you are imagining that the resonator only lets
> the antenna absorb a bit more of the energy that passes
> within one antenna-length distance. If that's all that
> it did, I wouldn't be the least bit excited, and those

Then dont. Fix your conception of electrically small. Hard to calculate doesnt mean "new theory required" or hard to understand conceptually.

> physics papers would never have been written. The resonator
> lets the antenna absorb energy which can miss it by
> thousands of antenna-lengths (in the case when the
> physical antenna is thousands of times smaller than
> 1/4 wavelength.)

I'd be willing to bet that your notion of electrically small is incorrect. Look at an archimedean spiral. How big should an antenna be from consideration of the unccertaint principle? In that case, is a straight line required? What changes if you consider 2 dimensional areas or 3 dimensional volumes? Would a 3-d volume of metal be an improvement over a hollow cube (it's bigger; has more metal). The last example just shows even a simple-minded picture cant be applied ind-iscriminately. So far, either you have tried to do exactly that with whatever I've provided or you really just cant tear loose of the classical picture.

1904. Cheap Telephone headsets

This is not really a problem. It is quite normal to be "Pissed Off"
when a circuit refuses to work properly. Bounce the offending circuit
off the wall, try again later when you calm down.

>my last
>effort has left me pretty fed up to the point of giving up so i hope
>someone can help.
> regards

Ugly (Dead Bug) construction is a quick and easy way to
produce a working circuit. As a general rule, the uglier
it is, the better it will work. If it doesn't work first time,
you don't have to etch a new PCB to modify the
circuit.

http://www.qsl.net/ei9gq/ugly.JPG

Happy Homebrewing.

Hello to all.

Does anyone still operate an HW-5400? Does anyone know of any good hints/kinks/mods pages out there for this rig? I have one that is receiving ok, but has transmitter trouble on SSB modes. The ALC circuit doesn't seem to be working properly (panel meter not working properly also in transmit), and the output spectrum has some spurious problems. The output can be driven to the full 100W level in both SSB and CW modes.

Thanks in advance.

Looking to trade:
1 Motorola Micor Tested Working W/ Control Head (Freuency Counter showed 800 mhz.)
1 Motorola Pulsar Tested Working W/ Control Head (Frequency Counter showed 150 mhz.)
2 Motorola Motracs Unknown Frequency Untested No Control Head

I was going to convert the 2 first ones for repeater use, but didnt want to attempt it in
case I blow them up. So I will trade all 4 radios for a working Converted for Repeater use
GE Master II or
Motorola Micor on either 2 meters or 220mhz amateur bands ready to use, Controller
Ready....

The Micor and Pulsar look in good shape and are working. The Motracs are ugly and
untested because there is no control heads.

Here is the info for the radios:

Motorola Micor:
FCC XMTR DATA: CC5010
FCC RCVR DATA: RC0071
MODEL #: T45RTA6B00AA
SERIAL #: 439CDS1200

Motorola Pulsar
MODEL: T1776A
RCVR: RC0047
FCC TYPE: CC3225
SERIAL: RR6210

Motorola Motrac #1:
MODEL: U43HHT-11300
TRANS TYPE: CC3009
SERIAL#: E-14787

Motorola Motrac #2:
MODEL: T43MHT-1190C
TRANS TYPE: CC3059
CABLE TYPE: 2
SERIAL#: Not Visible

I would prefer a local trade (Redding, CA.) but will ship in the US.
If interested or have a
question, Reply to cobra@no-spambudweiser.com

Ol� Horta...

As datasheets deles eu tenho aqui com as curvas para vc ver a opera��o
na frequ�ncia desejada. Tentei scanear mas n�o fica leg�vel.
Realmente o 2N4427 dar� 1W de saida em 175 Mhz com 100 mW de input e
ganho de 10 dB garantido, mas em 300 Mhz s� poder� dar (no limite m�ximo
e n�o recomendado) 700 mW com excita��o de 100 mW, ou seja um ganho de
apenas 8,4 dB.
O 2N3866 � que trabalha com at� 28 V de fonte. Para 13.8 V de fonte, ele
d� (tamb�m no limite) 1 W com 100 mW de excita��o e ganho de 10 dB. Em
300 MHz ele d� uns 300 mW com a mesma excita��o. Ele opera melhor com 28
V, com mais ganho e mais pot�ncia de saida. Tudo isso em classe C.
O maior problema � que o 2N3866 pode dissipar a 25 C at� 5 W e o 2N4427
apenas 1 W.

And the key answer is NO. Resonance has nothing
to do with the amount of energy intercepted by the
antenna.

>More
> specifically, if we connect just a resistive load to
> a short dipole and adjust that resistor for maximum
> received power, can we receive even MORE power if we
> then connect a lossless tank circuit across that dipole,
> then re-adjust that resistor value for maximum power?
> These papers imply that the answer is yes:

My answer is also yes, but not because the antenna
intercepts more power. It is because the circuit is made
non-reactive by being resonated, allowing more power
to flow into the load instead of being re-radiated. In other
words, it is a circuit matching issue.

P = E * I * cos(theta)

When theta is 0, power out of the circuit is maximized.
Theta is only 0 when the circuit is non-reactive, and we
can make it non-reactive by resonating it.

I did just that for a pair of FRS Kenwood handhelds I use while hunting. Find a schematic for the speaker mike that works for the HT in question, and rewire the headset/boom mike to match the "pinout" of the speakermike. It helps if you know mic impedance beforehand, so you can shop around for a headset that has the right microphone characteristics. Easily done. At worst, you might have to add a small capacitor or resistor inline.

Had a second thought about the application for NE614, it seems fairly
easy to use. Nominal input to product detector for AM and SSB/CW is in
the region of 5 to 20mV RMS with MC1351 and TBA120. Not sure if it is
practical to combine the demodulator for all three modes, the price
for a second NE614 isn't too high, and you loose RSSI function for the
device used for ssb, this is the second argument for using a different
device for FM - and it might serve as S-meter driver for all modes

if somebody is interested, the file showing the G8IBR type MC1351P
multimode detector is 8kb gif, send me a mail (it is easier since I

But because of resonance, the circuit stores energy from
previous cycles. That is critically important, and that's
why "impedance matching" is too limited to truely describe
what is happening. Also, if the wavelength is long, the
resonant antenna can absorb energy which would other
wise miss it by a large number of antenna-lengths. That
is part of impedance-matching too, but it is hidden because
"impedance matching" in this situation is only one
viewpoint, and it has serious limitations if expanded insight
into the physics is the goal.

I see the difficulty. You seem to be arguing that BECAUSE
it is an impedance matching issue, it IS NOT a matter of
resonance. As if there was one right answer, and we must
get rid of any other viewpoints. This is improper, in my
opinion, because in order to understand anything completely,
you have to look at it from all possible viewpoints. I realize
that I violate some particular belief when I say such a thing,

and it causes people to raise objections and become
argumentative.. If we're SUPPOSED to view it only
as circuit matching, and never in any other way, then what
say is sort of like blasphemy. It is an alternate "religious
position" which, because it is ALTERNATE, is perceived
as being incompatible. No. It is only alternate. But if you
believe that there is "one right answer", then the
existence of alternate viewpoints must be "wrong"
somehow. (And from my viewpoint, if there are several
ways to view a phenomenon, and they give differing
insights, then the focusing on "one right answer", and
the attacks on other viewpoints, THAT is the
blasphemy.)

>
> P = E * I * cos(theta)
>
> When theta is 0, power out of the circuit is maximized.

Right. Heh. AT RESONANCE, power out of the circuit is
maximized, and if the freq of the incoming wave should
change, it's no longer at resonance, so the effect doesn't
work. To make it work, sweep the frequency of the
transmitter around until resonance is achieved in the
receiver.

Johnathan Swift had things to say about big-endian versus
little-endian warfare in GULLIVER'S TRAVELS. It is
particularly appropriate in any physics debate, since often
the fight is over the One True Way to "crack" a
complicated "egg."

You may be holding an unwarranted assumption about
where energy is when it is in transit. There is no
classical physics requirement that the energy be in
any particular place when it is not interacting
with matter. It is conventional to say that energy
density is proportional to the square of the field
strength, but it is not necessary.

Feynman had something say about this. I'll
see if I can find the section and give you
a reference.

> "Load matching" implies that

> it is "reaching out" across a non-trivial area.
> Call it "load matching" to hide the details, or "energy
> sucking" if you like controversy! :)

Consider this. The distant transmitter has two antennas
which create an interference pattern. The location
in space where the pattern shows complete cancellation
has zero thickness. If a dipole was there, it would receive
no signal. But move your dipole to where the signal
is strong and let the near field build up. Now move
it to a null in the pattern before the near field
dies out. Since the true null is near zero thickness,
the near field ought to stretch beyond that and continue
to pull in energy from the field.

But it doesn't.

Measurements are real. Theories are judged on their
usefulness.

> Any other
> explanations are therefore distortions, or perhaps
> blasphemy, but in any case it must be stamped out or
> at least prevented from contaminating the One True
> Explanation.

Well, I sort of follow the teachers equivalent
of the Hippocratic oath "do no harm". Which means
I am reluctant to support "alternate" explanations
when I suspect that they will cause confusion
later in the educational process. It is my value
judgment that most people are better served by
teaching "the standard" explanation. If the
"standard" explanation has short comings, that
needs to be admitted. Alternate explanations
are ok, but need to be clearly labeled as such.

Throw in "as if" every so often.

That might be all very well where you live, Reg, but out here
on the west coast of North America, beautiful women with nice
smiles are a bit common, and occasionally, even dangerous -
to one's pocketbook if nothing else. Besides, it's sometimes
difficult to tell what kind of smile, and from whom, our
hard-pressed electric motor repairer might consider acceptable.
I've had better luck just being a hat-in-hand good-ol'-boy.
Then I don't have to turn the fellow down when he asks me for
a date.

> dr.d

This idea of Jan-Martin's doesn't originate with a particular device. The basic idea is that a double balanced mixer is used for CW/SSB, with a locally generated oscillator signal in the other input, which beats the incoming signal down to audio frequencies.

For AM, if you put the incoming signal through a limiter, you will get a locally generated constant voltage signal at the carrier frequency to use instead of a BFO; again that signal beats the incoming signal down to audio frequencies.

I saw this scheme for AM in an article about the MC1496 double balanced mixer 30 years ago; they even claimed that if signal levels were right, no external limiter was needed. And you'd see the scheme in various mult-mode detectors over the years. The National LM373 data sheet or application note showed this scheme, and there were some Plessey multi-mode detector ICs that also suggested this. And Ralph Burhans had some articles twenty years ago, in Byte and 73, on Loran C receivers that used ICs intended for AM/FM broadcast radios, which used the FM detector in this way.

A lot, though not all, FM detector IC's use a balanced mixer as part of the design. You do have to look at the specs to make sure you've scrounged the correct type. The advantage of using this is that such ICs are often handier to come by, like in scrap circuit boards, and the limiter is already there for the AM scheme. And of course, if you want to detect FM, the IC can be used for it's original purpose.

I haven't actually tried it, and I do wonder if there may be problems with strays, such as the BFO getting into the wrong area, and switching points that are physically only a few pins apart.

You could do the same thing with an MC1496 or NE602 double balanced mixer, and external circuitry. Back when the Signetic PLL's were commonly seen, one of which had an extra balanced mixer for AM detection, someone had an article using the NE561 for FM (the voltage out of the phase detector tracks the FM signal) and AM (with the extra balanced mixer mixing the incoming signal with the VCO signal locked to the incoming carrier), and then he used CMOS gates to provide

a bfo signal (for CW/SSB) and limiting for better FM reception. Of course, he was doing it all at 455KHz.

One thing about the multiple conversions in your original post. If you can get the selectivity you need, you don't need to convert to a lower frequency. Indeed, if your project isn't high performance, you might get by with not too narrow selectivity; there are plenty of CW/SSB receivers that have very little selectivity before the audio chain.

But with FM reception, you may need to convert to a lower frequency even though a higher IF provides enough selectivity. For narrow band FM, the deviation will be a small percentage of the center frequency, and if you have a high IF the recovered audio may be low. That's why you still see FM receivers that convert to 455KHz.

Perhaps,if you can't figure a way to use it you could build a voltage doubler with the large filter caps,and some good sized rectifiers,and feed that to the hi frequency switching circuit(s)..that may work.. instead of finding a 3-phase supply..

Just an idea... may not be a good one,i'm not one to judge.. it's late..

1931. ZRS 30m QRP transceiver - ultra modern design

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-12 00:00:00 UTC
From: LA8AK@online.no
Message-ID: <38caf536.287777761@news.online.no>
Source record: 62546

see http://www.zrs.org/cqzrs/299-2027.pdf for S57NAN modern QRP
transceiver using AD631 and NE612 with 4194.3kHz xtal filter in RX
The VXO is pulled 14294-14324kHz using varicaps
PCB and mounting is shown
Another unusual point (as for QEX) is that you can read back issues of
the magazine from the radio club, could it be an idea for other IARU
organisations?

Thanks Reg and Richard for your suggestions.

In fact an engineer colleague has just finished putting together a class-E 160m PA originally designed by Fritz Raab, this together with a class-S PWM modulator.

This is more complex that I'd like for use on 160.

I'll look at your idea Reg. I do want to keep the design strictly based on the KISS principle to see how simple inexpensively it can be done with acceptable results.

I was considering the PLL route as I've found a very simple suggested building block on a web site.

Once again thanks for both your input.

Regards

Phil G4ZOW

Michael
Although I have some practical experiences, all the suggestions
presented are based on technical notes by G8IBR.
NE562 seems interesting device, works to above 10.7MHz, although I
don't believe it is good for NBFM, once tested monostable detector on
455kHz, but detected audio was weak. NE564 has been used in SATTV
70MHz demodulators, but deviation was 10MHz

For AM PLL demodulators is it any problem to decide the phase angle
between LO and RF signal? NE562 seems interesting in combination with
MC1496P or SO42E.

Again miss information from somebody who have tested such in
practice, so far I only know that G8IBR. LA7MI, SM6HYG, and myself has
tested this sort of AM detection. Many admits it is interesting, but
seldom seems to be capable of connecting few components

TBA120/SN76660N (SO41) was very popular device in Nederland (and
Germany) in applications for VCO, PLL-detector, mixers etc, and SO42P
has been used in Germany for several applications. Some handbooks and
sites mentions an audio upconverter I made using TBA120/SN76660N, but
I prefer using MC1496P. Have even used it in CW demodulator.
MC1310P - stereo decoder - is another device which will work for
several other applications than it was planned for, one such is audio
oscillator and mixer.

In order to be capable of using such devices you need a detailed
circuit diagram, such was shown for TBA120 in Radcom in 1973 together
with information about NBFM quadrature circuit details for 455kHz.

>
It is interisting that you should mention cell phones, as I was going
through some on my junk and found a OKI 3 watter with a 45 Mhx to 455
IF section unfortunataly I have no data in it an it looks like it might
take several days to dope it out. I dont suppose there is any chance
you have a similar unit and already have the info?

Other than that I have droped the TV IF idea and decided on using a
MC1371 for 45 to 455 and FM detection and a TDA1572 for 455 to AM
detection with a 602/612 for SSB product detection.

Your best bet is to pick up a copy of the ARRL Handbook - one from the 1950's or 1960's - on EBay - they go for only $4 or $5. -- and all have tube receiver designs from simple to quite sophisticated. QST is available on CD Rom from www.arrl.org

I apologise for the previous blank posting. I hope this kind of part will be useful to the home brew crowd.

Bob, KE6F

For Sale: 4 each Siemens/Infineon "Smart Display" 4 character 5X7 matrix Red LED display. Siemens/Infineon part number DLR 2416. Each unit contains an ASCII character rom, which will display numerous characters, numerals and other symbols. Data is entered in a 7 bit parallel format. Two additional pins allow for addressing each charactor position. Also has chip selects so an array of these be stacked end-to-end for larger displays. These units are packaged in wide dip packages with 0.1 inch pin spacing and 0.6 inch between the rows. A 40 pin IC socket will hold two of these display perfectly. . Full specs on the infineon web site http://www.infineon.com Units currently sell for $12. on the Pioneer-Standard web site. $13.20 for the four items post paid conus.

Thank you for the read

My wife of thirty years would be distraught if I suddenly changed my sexual orientation. One has to choose one's words carefully on this newsgroup. I wrote the above without carefully thinking through all the ramifications. I'll have to cut back on the consumption of roast beef and cold beer. The roast beef, in particular, is hard on the thought processes.

There was a multimode detector project article in QST about 5 years ago
that used an FM IF (NE604?) for FM and a NE602 for the AM using these
techniques.

Even if someone gave you a Millen, please THROW it away. The contactor is almost exposed, and with the weight of the wire it WILL be exposed. Look around for an Amfenol multi pin, take it apart, remove the pins and use only the center pin. That is what i did for a 3750 volt supply. Mine has a diameter of 1 1/2" and the pins are heafty. They are all over junk boxes in fleamarkets. 73 De Constantine

You might want to look at the definition of Q before settling
on this description. Then look at the Q for a resonant circuits
with both large and small Q, i.e., { f \over\Delta f }. The
result of storing energy means your bandwidth goes DOWN.
Why? Because the signal cant change faster than you remove
the energy and remain distinguishable from the that coming
in on the next cycle. By making the antenna small and resonant,
you lose bandwidth. Since you are storing energy longer, at
least in principle, you can make up for the small size by
sacrificing bandwidth.

> what is happening. Also, if the wavelength is long, the

> into the physics is the goal.
>

No. The insight is when you realize just how interrelated all
of this and how the puzzle pieces fall into place so that you
don't need to invent new ways to explain ordinary events.

> I see the difficulty. You seem to be arguing that BECAUSE
> it is an impedance matching issue, it IS NOT a matter of
> resonance. As if there was one right answer, and we must

Resonance IS an impedance issue. By definition, resonance occurs
when Z = 0. Impedance matching is obviously an impedance issue.
It may or may not be as obvious, but the boundary conditions at
the dielectric interface of the antenna and the media surrounding
it, completely determines the impedannce mathching.

> say is sort of like blasphemy. It is an alternate "religious
> position" which, because it is ALTERNATE, is perceived

Don't start with the all viewpoints are equal bit. That may
fly for religion, but here you need to provide some evidence

of this "energy sucking". According to your assertion of a
"grab" over 1000 wavelengths away, I should be able to
set up one of these and a measure a drop in field stregth
several counties away. That is, of course, unless it also
creates a replacement so you cant tell but do violate
conservation of energy.

> as being incompatible. No. It is only alternate. But if you

Telling people that gravity occasionally makes things fall "up"
doesnt make it an alternate approach merely because one doesnt
understand the way a volcaano erupts. You cant just lump effects
you don't understand in with what you think would be a cool cause.

> believe that there is "one right answer", then the
> existence of alternate viewpoints must be "wrong"

In this case, it is wrong, regardless of whether it's blasphemey.
There may be better theories of everything, but you should cut
your lossage on this one.

> somehow. (And from my viewpoint, if there are several
> ways to view a phenomenon, and they give differing
> insights, then the focusing on "one right answer", and
> the attacks on other viewpoints, THAT is the
> blasphemy.)
>

It's usually best if whatever approach one takes remains compatible
with observed phenomena. Fields reaching out of the deep and grabbing
energy (stealling joulery, perhaps?) is not consistent with anything
that has been reported.

There's a little more to it than that, John. Depending on what you want the filter to do, it may reside in software for a DSP chip, or perhaps on an ASIC or some other programmable hardware. Unlike conventional filters, the characteristics of a DSP filter are *programmed* rather than defined exclusively by the hardware.

There is, however, a place you can go for more information. Steve Smith has an introductory text out, and he's posted the entire contents on the web:

http://www.dspguide.com

Another excellent text is Rick Lyons' book, which I'd strongly recommend if you want to explore further. This DSP stuff is a great area to explore. Good luck!

>
> But because of resonance, the circuit stores energy from
> previous cycles.

That's your assertion, but saying it doesn't necessarily make it
so. A *high Q* circuit stores energy, but there is no requirement
that a resonant circuit be high Q, nor is there a requirement that
a high Q circuit be resonant. All that is required to have a high Q
circuit is for the ratio of reactance to resistance to be large. That's
very different than the criteria for resonance, where inductive and
capacitive reactance have to be equal. Both could be negligible
compared to resistance, and the circuit would still be resonant,
but Q would be very low.

Now a very short antenna (in terms of wavelength) is extremely
capacitively reactive. It also has an extremely low radiation
resistance. So a short (unloaded) antenna *is* high Q, but that
is regardless of whether it is resonant or not. Resonance has
nothing to do with the amount of energy storage a very short
antenna has. Nor does resonance have anything to do with
whether the antenna intercepts energy or not (for a different
reason).

Note that I said that a short *unloaded* antenna has a very high
Q. The moment you load it, in order to extract energy from it,
the Q drops sharply. So if you are trying to pull energy from this
circuit, it isn't an extremely high Q circuit anymore. And if you
don't pull the energy from the antenna, it will be re-radiated
and lost forever. Catch 22.

> into the physics is the goal.

Again, that is just your assertion. As I mentioned in a previous post, there is no localization of energy until the quantum probability wave function collapses. If any part of a photon encounters a charged particle in the antenna, the wave function collapses and *all* of the photon's energy is transferred to the charged particle (usually an electron).

The photon energy is E=hv, where v is frequency and h is Planck's constant. The "size" of the photon is inversely proportional to its energy. Low energy, and consequently low frequency, photons are very large. Or said another way, they have a large wavelength. But the energy of the photon is not localized until the wave function is collapsed. You can't say that some of it misses a nonresonant antenna while a resonant antenna "sucks" it in. That's not correct. The quantum is all or nothing. It is the smallest unit of radiant energy that can exist at that frequency. If the antenna receives any of its energy, it receives *all* of its energy. That's true regardless of whether the antenna is resonant or not.

Now I put "size" in quotes in the previous paragraph because the size is not a classical size. What is meant is the probability density function has a large non-zero area. We can't localize the photon, or its energy, until that wave function collapses. The presence of charged matter in that area of non-zero probability can collapse the wave function, localizing the photon and its energy at the position of the charged particle. There really isn't a classical equivalent of this, but the classical explanation that the presence of charged matter distorts the permeability and permitivity of the space in its vicinity so that the field lines converge on it says a similar thing, though it is physically inaccurate. (The math works, but the physics doesn't. We thought it did at one time, but we have a better understanding now, and know that it does not.)

> the attacks on other viewpoints, THAT is the
> blasphemy.)

You seem to think this is a religious argument. It isn't.
Nature either works a certain way, or it doesn't. As we
increase our understanding of the way Nature works,
we may at rare intervals have to accept a paradigm
shift, and view Nature in a different way. In other words,
our previous understanding was *wrong* in some way,
and we have to adopt a new view which is not wrong
in that way, but our new view still has to be right in all
the ways the old view was right.

We still probably don't have the whole story, but we
now know that any explanation that is wrong in that
old way is still wrong, and any explanation that violates
things that we now know are right, is also wrong. Your
hypothesis falls in that category.

Now sometimes we can have several alternative
explanations, and none of them seem to violate
anything that we know is right, or fail to denounce
anything that we know is wrong. In such cases,
we apply Ockam's Razor and choose the simplest
explanation that adequately explains all observations.

As another poster said, we can explain anything if
we throw in enough hidden variables. But Ockam
says that the explanation with the fewest such
hidden variables is the one we should embrace.

Einstein put it this way, "An explanation should
be as simple as possible, but no simpler."

>> P = E * I * cos(theta)
>>
>> When theta is 0, power out of the circuit is maximized.
>
> Right. Heh. AT RESONANCE, power out of the circuit is
> maximized, and if the freq of the incoming wave should
> change, it's no longer at resonance, so the effect doesn't
> work. To make it work, sweep the frequency of the
> transmitter around until resonance is achieved in the
> receiver.

This equation describes the transfer of energy from the
antenna to the load. It has nothing to say about transferring
energy from photons to the antenna.

> Johnathan Swift had things to say about big-endian versus
> little-endian warfare in GULLIVER'S TRAVELS. It is
> particularly appropriate in any physics debate, since often
> the fight is over the One True Way to "crack" a
> complicated "egg."

Well, not if one of the ways works the way we understand
the laws of Nature say it must work, and the other way
requires us to discard fairly fundamental and well tested
laws of Nature in order to embrace it. If we were to embrace
your hypothesis, we'd have to revise most of QED. Now
QED works very well, we don't know of anything that it fails
to properly explain (within its scope), so we're very loath
to have to discard it just so you can have your energy sucking
resonant antennas.

One thing to watch is that the front end may not be all that stable. It
will be running at fairly high frequencies, and is intended to be locked
to a reference frequency. Even in the old days, nobody worried much
(no could they do much to improve) stability since the IF of a TV set
is relatively wide.

When you start dealing with narrow band signals, the stability of the front
end may be an issue. I've certainly thought about making a nice
general purpose receiver with a TV tuner as the front end, but I don't
think it would be stable enough to be useful (though for wide band signals
or IF bandwidths, it may be fine). Locking it would get around the problem,
but the channels are of course 6MHz apart, and the prescaler in TV tuners
tend to divide by so much that you can't get narrow steps.

Another point is that if you scrounge up a 45MHz filter for the
first IF, you might want to do some more scrounging and scrap the TV
IF strip. At least some old cell phones had a 45MHz first IF, and
scrounging one would get you the needed filter, and a whole narrow
band IF strip. All three cell phones I've taken apart, all the clunky
older kind that nobody wants but the parts are nice and big, had
high first IF's and converted down to 455KHz for amplification and
detection. The advantage is that you'd also get a crystal to make
the converstion from the first IF to 455KHz. The disadvatange is that
two of the three cellphones had an IF higher in frequency, somewhere around
80MHz which may or may not be a problem in your project.

Some of those cellphones have the IF in a nice little module, relativley easy
to extract from the rest of the circuitry.

Once you've converted to 455KHz, you could then add a narrower filter
for AM and SSB, or use Jan-Martin's scheme to turn the FM detector into
a multi-mode detector.

I found the following info later in this list.
8 each Ma-Com Model MA-86501 Gunnplexers for sale
Original freq was 10.525 Ghz, and looks like he retuned them to 10.400 Ghz.
They were offered by Bob Partain K6OHH
e-mail is k6ohh@qsl.net
Hope this helps, if not I printed out the entire post, and will send it to you.

Well, for starters, Sec. 3 notes that the theory was developed to explain explain the discovery of the field described in Sec 2 and references 1-7. Look at the citations given for references 1-7. Second, the theory hinges completely on a non-zero photon mass and while he asserts the photon mass may be very small, I didn't see an estimate of how small it could be before invalidating his data. The limit on the photon mass at the time of Jackson, 2nd edition, is < 4 x 10^48 gm or equivalently it takes more than 10^20 photons to equal the mass of one electron as an upper limit. Since the impetus for this theory appears to have originated from experiment, it would be useful to know what the theory predicts it should be. Either it was left out or I didn't see it, but I would think the data would provide a lower limit where the effect wouldn't have been noticeible below.

Now, any non-zero photon mass allows the theory to be at least in the running if it's consistent with observation. But, it's always been the case that a non-zero photon mass requires fixing the current models. You need only look at the qed lagrangian under the replacement of \Psi -> exp(i\phi) \Psi to see that a photon mass breaks the gauge invariance. Any non-zero mass leads to most of the effects mentioned like longitudinal polarizations, light not travelling at c, etc. What isnt there, in the paper, are independent data that an effect exists in need of the theory. In addition, the statements regarding weinberg-salaam (GWZ in this paper) are misleading. Yhe photon mass wasn't ignored, it's explicitly zero by construction so that E&M retains its gauge invariance, and charge is conserved.

Thanks

Just buy one of the low-cost DSP evaluation kits sold by TI, Motorola
or Analog Devices, and write your own filter software for it. They cost
about $100 and come with development software.

Provided, of course, that your \phi is not a constant. And strictly
speaking, you should not look at the QED lagrangian (because that one
_is_ gauge invariant) but to the QED lagrangian with a mass term
added, e.g. the Proca lagrangian.

[Bilge gives a perfect guideline for further study here, but I thought
I'd turn it into a simple answer, as some posters sometimes ask for.]

But they _could_ have considered the case with broken gauge invariance.
In fact they did break the rest of the gauge invariance, so why not the
photon too. It is in that sense, that the photon mass was ignored.

And with good reason. Since it isn't observed, it would just be an
unnecessary complication (for a "standard model", that is).

I really get tired of writing \phi(x) rather than \phi (actually, I get
tired of writing \phi, but I dont think ï¿½(x) shows up on all systems,
not to mention being in violation of the rfc's). I mentioned the qed
lagrangian specificallly because it is invariant to point out that adding
the mass term ruins it.

>[Bilge gives a perfect guideline for further study here, but I thought

It requires a deliberate choice to arrange the four fields into an
isodoublet and a particular choice for vacuum to obtain a massless
photon. I would consider "ignored" to mean not making such a choice
and writing off the unphysical results as unimportant or artifacts.
They can't have not considered the possibility of a massive photon.

>And with good reason. Since it isn't observed, it would just be an
>unnecessary complication (for a "standard model", that is).

Since I've previously seen several claims (by the claiments, even)
for new forces . Remeber the 5th-force that was supposed to work aggainst
the gravitational force but was proportional to baryon number and had
a range of something like 100 meters or technicolor (which had some
neat features, but doesn't appear to have panned out)? I am dubious
of claims for more particles that we don't need. We still havent found
all the ones we do need. The standard model must obviously be incompplete,
but more free parameters go the wrong direction. Especiaally when the
only data and the theory originate at the same place and there's been
at least 6 years for someone else to produce one.

Hello--

Actually, IIRC the Tesla Coil relies on a high resonant Q for its voltage-stepup
capabilities, and in general high-Q circuits don't allow for a lot of information
bandwidth.

Also, a typical Tesla Coil is physically a small fraction of a wavelength and hence
not an efficient RF radiator. You'll need to string lots of wire between trees, instead.

BTW, if you did key up a monster Tesla Coil into a large antenna, you'll generate
RFI, EMI, HAI, EOI, CBI, CTI and just about every flavor of "I" you can-- and can't--
imagine. So, unless you want the Feds, your fellow radio amateurs and (worst
yet) a bevy of irate CBers on you like chickens on a June bug, stay in-band and go
for a clean signal instead.

William,
This wire will work just fine. The potential from one winding to the one next to it is quite low. The potential from one layer of windings to the layer above or below it isn't much either. Insulate the windings from the core, add insulation at the 'ends' of each wire as it comes out of the winding, and you'll be fine. You can also mount the transformer on insulators.for more 'peace of mind'.

You have lost me. Does this mean that if a photon has a mass, the photon's fields will not conserve energy, depending on the reference frame between the photon and an observer?

Scott

Before I go on about this, I'd like to know, have
you read either of those physics papers? If not,
then you are arguing about things being relayed to
you second hand and possibly misinterpreted by me.
The "energy-sucking antenna" discussion is a discussion
of those two papers. If anything else, reading them
will give you powerful ammunition for defeating my
arguments. And who knows, maybe reading the actual
arguments presented by professional physicists will
be more convincing than any arguments I can present.

I doubt it though. This whole thread is starting to
look like something from a debating contest, where the
object is to win at any cost, and where all sorts of
"debating tactics" become acceptable. If this is a
science discussion, then attaining new insights is the
goal, and "trying to win" is not.

>replace a SMD transistor in a densely-packed circuit?

I have done it a couple of ways.

One way is to use a fine solder braid and a fine tip and move the
braid around a given pad until almost all the solder is gone.
Slightly pry up the device lead while hot using the iron tip or a tiny
screwdriver. When cool, use the tiny screwdriver tip as a lever if
necessary to break any remaining tin-lead bond.

Another way is to cover the transistor in hot solder, thus getting all
connections melted simultaneously. Then the part may stick to the
soldering iron tip and can be splatted down on the table or scraped
off, or a solder-sucker can be used to take up the whole mess. The
board can be cleaned by solder-sucking and/or solder braid.

Be careful when using braid. It can be surprisingly effective, but if
one does not keep it hot it will stick, which means it is soldered to
the pads, and then one is pulling on the pads. So use sufficient
heat, but not so much as to peel board runs off. One can feel the
braid stiffen as the solder solidifies.

Put one lead down first by holding the part and soldering one lead.
Make sure the part is in position before soldering the other leads;
re-melt the first lead and move the part if necessary. Then solder
the others. Then inspect each connection with a magnifying glass.

Be sure to try these things out a few times on scrap boards before
doing it for real.

The tactics employed by scientists are closer to debating
than you might allow. Can you imagine an exchange of letters
between a pair of competing scientists where one backs down
and says, "By George, you're right - my interpretation is
nonsense and I've completely bungled this analysis". It
never happens, at least not in public. It's not up to them
to resolve their differences - the test of time is the one
that counts.

Hi All,

I'm looking for a Tube Tester that is able to test at least the following
tubes;
12AT7/6201, 6AH6, 6DC6 and 6CL6.

Would a Hickok 533, or 539 be able to test these tubes?
Since I like the Replace/Good indicator on the 533;-) I prefer the 533, but
I don't know if the 533 can test these tubes.

If not, What other tester would accept the tubes?

Thanks in advance.

Best regards, Francine.

Here's what I'm looking for: handheld-type battery-operated calculators, mostly the LED-type calcs from the 1970s, the ones with the reddish, blackish screens, often with glowing red numbers, as opposed to those you see most often today, with their typically grayish LCD screens (except for HPs -- love em w/ any screen!). I'm looking for all makes, all models, as long as they are cosmetically clean -- see partial list below. (The only calcs I don't care for are those made by Texas Instruments.) Anyway, if you've got the old manuals, cases, chargers, so much the better. Just drop me an email (floetay@aol.com) and let me know what you have and the condition it's in, and we can go from there. Thanks!

Calcs I'm interested in include, but are not limitted to those made by: Hewlett Packard (all models, both LED and LCD), Adler, American, APF, Apollo, Aries, Aristo, Berkey, Brother, Busicom, Caltronic, Candle, Citizen, Colex, Columbia, Corvus, Craig, Crown, Dataking, Decimo, Dictaphone, Digicomp, Dixon, Edmund, Enterprex, Facit, General, GIC, Hanimex, Hermes, Iain Jones, Ibico, JC Penneys, Kingspoint, Litton, Logitech, MBO, MITS, Master, Melcor, Mintron, Monroe, Omron, Ordibel, Panasonic, Pico, Pye, Ragen, RBM, Regan, RFT, Ricoh, Royal, Samsung, Sanyo, Sears, Sinclair, Spectrum, Sperry, Summit, TKS, Toshiba, Universal Data, Verax, Victor.
Good golly -- can you believe there were once about 220 brand-names in all?

>
>You have lost me. Does this mean that if a photon has a mass, the photon's
>fields will not conserve energy, depending on the reference frame between
>the photon and an observer?
>

Nothing but aesthetics (backed by the 11 decimal prediction of the electron's
magnetic moment) prevents the photon from having a mass. Energy and (almost)
everything else) is still conserved. The dirac lagrangian is:

\*Psi (i\gamma^{\mu} \partial_{\mu} + m) \Psi = 0.

\*Psi = conjugate

If an electron is to be free to reference things (like fields) from it's
perspective (gauge invariance) then you would argue that the phase of
a function (your choice of coordinates) doesnt alter any physical
result and the physics depends on quantities like |\Psi|^2. In other words,
replacing \Psi by exp(i\phi)\Psi doesnt change the physics. If
you do that above:

exp(i\phi) \*Psi(i\gamma^{\mu} \partial_{\mu}

+ m) exp(-i\phi) \Psi = 0.

you get (with the wavefunction being implicitly a function of the
coordinates of course, so I don't have to write \Psi(x), too.

exp(i\phi)\*Psi (i\gamma^{\mu} \partial_{\mu} exp(i\phi) \Psi
+ exp(-i\phi) m \Psi = 0.

and since, in this case \phi is constant, the derivative factors
out and you are left with the same equation you started with.
Well,this isn't very interesting because all it does is tell you
a global phase doesn't mean anything. We want each electron to
be able to choose it's phase independently and be able to use the
same equation to describe the world, or in other words, the phase
```

\phi is an arbitrary function of the position (x == (t,x,y,z) here)
\phi(x). In this case it does matter that you are taking a derivative.

\partial (exp(-i\phi(x)\Psi) =

i\Psi exp(i\phi(x)\partial \phi(x) + exp(i\phi)\partial \Psi

and the new lagrangian is (after again factoring out the multiplicative
factor \exp(i\phi) left in each term:

*Psi ((i\gamma^{\mu} \partial_{\mu} + m + i(\partial\phi(x)))\Psi = 0.

This is NOT gauge invariant as it sits because by changing phases,
you added a new term. The solution, is to include that into
a definition for a gauge invariant derivative, which allows the
derivative to transform as well. You introduce the vector
field A_{\mu} such that the new derivative D, transforms:

D_{u} = \partial_{\mu} - iqA_{\mu}

(And since I know the answer, I've put the charge q in
explicitly).

And A transforms as A -> A + (1/q) \partial (\phi)

You'll note the similarity between this and the classical
gauge transformation. The vector field A has a kinetic
energy associated with it and since maxwell's equationnns tell
to that you can add the term (properl normalized):

(1/4) F^{\mu\nu} F_{\mu\nu}

to the lagrangian. This is already invariant so it doesnt
need to be "fixed". However, if the field has a mass term,
the equation is no longer gauge invariant. This works out okay
because no one has detected a photon mass. You can get a
mass, but it requires a new particle - the higgs.

In GWS (the term used in the paper for weinberg salaam), they
were unitinting the weak and E&M interaction, but the W+/-
and Z are MASSIVE, not MASSLESS. I'm not going to even attempt
to do this in any detail, since a book would do a better job
with clearer nomenclature. However, the salient features are
that you get 4 massless fields from gauge invariance. From
there, you can obtain a lot of things corresponding to
different vacuums, but GWS deliberately chose the vacuum
to get a massless photon and conserve charge. I don't see it
as an accident or a result of neglect.

==========
It is a fact that the strength of the radiation field is independent
of the size of a small antenna measured in fractions of a wavelengths.
It depends only on the power input and on the antenna's power
efficiency.

"Reciprocity" reverses the argument for a receiving antenna - in a
field of given strength the maximum available power is independent of
the size of a small receiving antenna and depends only on (the same)
power efficiency. The theoretical antenna can be as small as you like
!

When discussing antenna properties it may simplify matters to think in
terms of ideal antennas which are, in themselves, lossless.. But be
prepared to accept some wierd consequences of field distortion unless
just a teeny bit of inefficiency is allowed.

I thought that came from you're comments. I'll have to find
the particular post. But it doesn't matter If it's 2 wavelengths,
you violate light travelling at the speed of light to
accomplish it:

source
/ your antenna
0 ---------x
\
\
\x
ray it supposedly captures

The ray it captures must obviouly not take the direct
path or else it isn't of any interest to your argument.
If both arrive at the antenna so as not to degrade
the bandwidth, the 2nd ray has to travel faster than
the first, since not only is the path longer, but the
antenna has to "reach out and grab" it, OR

It has to violate causality to know something will be there
before it is, OR

It has to violate causality because the source would have
to redirect something that may have been emitted already
(unless this "effect" also depends upon distance from
the point of emission),

> Jeeze, no wonder you're attacking "energy sucking." If
> you think it's supposed to operate over distances of
> 1000 wavelengths, something seriously screwy is going
> on here.
>

No. I was attacking it before that. Since I thought you said something to the effect of 1000 wavelengths, I used that number to show how rediculous it sounded in context. However, the context isnt required to validate that point.

> Are you aware that this whole thread is about two papers
> from physics journals? Have you read them? Do you
> have access to a physics library?
>

If you'll recall, I asked you to cite them. I cant believe they say the same thing you imply, though I'm sure you do. Are you also aware that even prl comes out weekly and is unlikely that every or even a substantial fraction of what is published there is intended to do anything but propose further investigation? You are claiming that something which, as you describe it, requires a rewrite of modern physics and the papers describing the effect has generated no interest? Have you checked to see if there exist responses? Or followups? Please cite them so I know exactly what the problem is supposed to be and if it's related to this thread in some way. Are you also aware that the objections I've posted are still objections regardless, since such an antenna isn't compatible with current E&M ig what you claim is true? I suspect it's more like misinterpretation. And just as a reminder, I am unlikely to consider anything at keelynet a physics article. I'll read it, but so far, they have a 100% bogusness quotient. I don't anticipate any improvement.

The same sorts of claims have been made for the cfa, but that theory, is totally wrong despite insistence by people in direct contact with the inventors and who won't address a single problem that I've pointed out with theory, and despite the fact that the thesis that contained it was accepted in partial fulfillment for a degree. If this happens to be related to the cfa, I'll state right here that it's wrong.

I've presented objections which in the context of current
E&M theory are valid. You haven't cited the papers as I've
asked and you've not shown that anything I've said is
incorrect. It's up to you to provide some evidence that
either E&M is incorrect or I am incorrect, since I believe
I've shown that in the context of E&M as it's known ,
what you've claimed cannot be correct. The citation will
at least let me know if you misunderstood the article or
whether E&M is history or whether the article is wrong.

But why would "we" want this?

> In GWS (the term used in the paper for weinberg salaam), they
> were unitinting the weak and E&M interaction, but the W+/-
> and Z are MASSIVE, not MASSLESS.

But usually the descriptions of this theory give no clear reason _why_
there is gauge invariance. Also Weinbergs own QTF vol. I (the chapter
about QED) and vol. II (the chapter about non-abelian gauge theories and
the one about the electroweak interaction) don't give a clear reason.

The reason you give above ("we want each electron to ...") would
indicate that it's just for our pleasure. But it is mysterious why
nature seems to have a preference for gauge theories.

I think there was an 833A linear in the ARRL handbook in the
early '90's but my books are all packed up for a move or I would
check.

Hi Willy,

It can be done -- don't let anybody tell you different! IMHO (and in the opinion of the ARRL throughout the tube era...) a regen is a very good first tube receiver project -- afterwards you can seek out receivers with more performance and features. Here are some links:

http://www.qsl.net/~n6ev/1957.html look at 1-tube (6U8) regen

http://www.algonet.se/~janax/myregen.htm

http://www.fix.net/~jparker/norcal/hamcom/regenlinks.htm

2021. Re: diode mixer questions

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-15 00:00:00 UTC
From: Ed Schick <schick@##us.ibm.com>
Message-ID: <38cff1a0_2@news1.prserv.net>
Source record: 62448
Cross-posted to: alt.engineering.electrical,rec.radio.amateur.homebrew,sci.electronics.basics

Your post doesn't include enough information to give
an exact answer. For example - you ask about input
and output impedance. You want to match both input
impedances. A) to the local oscillator (the point labeled mix
on your diagram) and B) to the IF (the point marked in on
your diagram). Then, you want to math the output impedance
(the point marked out on your diagram) to the impedance
of the next stage. The caps drawn in your circuit ar most likely
for DC blocking. No need to calculate the diode's impedance.
Typically, there would be more components between the local
oscillator and the input to the mixer. These would likely be an LC
filter designed to block frequencies bove about 2X the LO frequency.
The output of the mixer would also contain filters, tuned to pass
the desired frequency and block others.

A single diode mixer is a real poor choice these days. There
are cheap and effective doubly balanced mixers available from
various supply houses, if your main interest is in creating a working
transverter. But - if you are experimenting and want to learn
about mixers, then go for the single diode variety as a first
experiment. But you're gonna need a bunch of good test gear -
signal generator, frequency counter, spectrum analyzer, attenuators
etc. I would recommend hitting the books before that, unless you
are fortunate enough to have access to a lab. An hour of reading
can replace hundreds of hours in the lab. And - if you have
laboratory equipment - you can put into practice in the lab what
you see in the books.

You ask about the resistor/choke. Take a look at your circuit.
If there was no means of developing a voltage drop (across
the resistor or choke) the signal at the bottom of the diode
would be grounded (the diode would be connected to ground).
You would have no means to get output to the next stage.
There has to be some amplification after the output - that
is not shown.

With a doubly balanced mixer, the usual input/output
arrangement is via transformer. Typically, you
feed the LO to the center tap of primary of the input transformer,
and the IF to one of the outer legs of that transformer -
the remaining leg goes to ground. The output (secondary)
of that transformer feeds 4 diodes, arranged in a ring like
a bridge rectifier. The output from the ring feeds into
a second transformer - the output from that transformer

feeds the next stage. I could spend a long time typing
what you can find in books - and doubtless I'd make
mistakes, so I heartily recommend a trip to the library.
Look for the ARRL handbook - it will have some
information on mixers that could get you started.
Also, somewhere around here I've got a book that does
a pretty good job of discussing mixers at an entry level.
If I can find it, I'll copy the pages that cover the subject
and snail mail you the copy, if you would like. Let me
know by E-mail if you want it - remove the # from
my address to send E. Ed

Most recent upper limit on the mass of the "standard model" Higgs:

230 GeV (with 95 percent confidence level)

(from an article two or three weeks ago in Phys. Rev. Lett.)

This means we should be able to find it with detectors available
within the next few years. If it's not found, the "standard model"
of physics is wrong. We'll then have to find another theory.

Hi Jan-Martin,

That sounds like a common stepper motor. If you do a web search, you'll turn up all sorts of info on driving steppers. Not too long ago I posted a short "tutorial" about them under some heading about a flatbed plotter over in sci.electronics.design. It should be available from dejanews, at least. But there's tons of stuff out there. The very brief explanation: drive the two windings with a sequence of DC levels, like so:

step winding 1 winding 2
1 +24V 0
2 +24V +24V
3 0 +24V
4 -24V +24V
5 -24V 0V
6 -24V -24V
7 0V -24V
8 +24V -24V
(repeat at step 1... Reverse the order of the steps to turn the opposite direction.)
The maximum stepping rate depends on the inertia of the motor and its load, and on how quickly you can change current in a winding when you turn it on or off. If you use higher voltage, but current limited, you can increase speed; and if you accelerate and decelerate in a controlled fashion, you can get to higher speeds. The steps listed above would normally be called "half-steps" I believe, so once through that cycle would probably cause your motor to turn about 30 degrees. 12 cycles through it would give you one revolution of your motor shaft.

You can often use a phase-shift capacitor to drive steppers from an AC source...

Cheers,
Tom

Imagine that :-)
I'm not the only one that has, the Motion Mountain online physics book I refered to a few posts back describes the uncertainty principle as a result of 'baths' or statistical analysis of a non-statistical instance, which again goes back to wavelets vs fourier, and something about loosing scattering matrix diagonals.

No spooky wave-particle collapse, because wave particles are solitons that have a wavelength, position and velocity.

I know some people objecting that if you cover on slit of a double-slit interferometer up, then the particle or photon's path is altered. The particle must be a wave, to have traveled through both slits. But consider the following:

Particles and photons are electro-magnetic solitons that travel through a noisy medium (the vacuum or aether)
A photon is a soliton that must travel in space
A particle is a soliton that loops in a circle, constantly running around the same tiny area of space.

A double slit interferometer is made of soliton-particles that are in a bath of noisy vacuum-foam.
When a photon travels through a slit, the slit functions as an antenna.
The photon is absorbed and re-radiated by the slit, and in the process of re-radiation, gets mixed with the vacuum noise.
The vacuum noise bandwidth or frequency components are dependant on the geometry of the interferometer (think of the Casimir effect & virtual photons).
Particles move because they are distorted, they distort the field around them and the distorted field has a wavelength that ends up functioning just

as a photons wavelength.
Likewise spooky tunneling and entanglement have meaning in terms of finite, non-pointlike particles that can deform, store energy and vibrate, and interact with the noisy nonlinear fluid they travel through.

Now you still have a vacuum with virtual photons, (which I see as noise) and you still do a sum-of-all-paths or path integral, but now there is meaning to it all, a mechanical basis that is understandable to crude minds like mine that get neurotic over wave-particle spookyness ;-)

Scott

Ok, now that you have discussed the receiving properties of atoms how about transmitting properties. If an atom emits some sort of radiation what would be the direction, and is it in the form of photons or EM waves?

It seems to me what you've discovered there is simply an example of
conjugate matching. If you "look back into" the little capacitor in the
field, you will "see" some source impedance. In a linear,
time-invariant system, I expect to maximize the power dissipated in the
load by making the load impedance equal to the complex conjugate of the
source impedance. If you come up with something different from that,
um, I might quit yawning... Sorry, but so far, I don't see anything new
here. As soon as you agree that the system is linear and time-invariant
(over the time span of our experiment, nominally), then it's going to
take a demonstrable deviation from what's predicted by linear circuit
theory to get me excited.

Cheers,
Tom

Ever notice the tendency for any prediction usually places the
ability to obtain verification just a shade over the edge of being
able to accomplish the task with existing equipment? If the
standard model is wrong, it will be really difficult to explain
why it works so well. I haven't looked recently, but if the higgs
isnt found where it's supposed to be, I suspect there will be
new reasons for not seeing it in the context of the standard model
before dumping it.

I knew about the article before you mentioned it, but I had to dig it out
to get the date. If only magazines would put their cumulative indexes
online, it would make things so much easier for those of us who remember
articles, but never bothered to memorize the issue. The ARRL actually
puts QST's index online, or so I gather, but it's in their members only
section which doesn't help the rest of us.

Anyway, it was QST for July 1993 that had the article, "A Synchronous
Detector for AM Transmissions" by Jukka Vermasvuori of Finland.

(Or maybe it's not the same article? Because it does not detect
FM; this one is strictly for AM.)

And the article was reprinted in some editions of the ARRL Handbook,
but I can't say for how many years or if it's still in the latest issue.

It has both a synchronous detector, with a PLL that locks to the incoming
carrier, and a "quasi-synchronous detector" of the type we are talking
about here.

What's interesting to this discussion is that it uses NE602s for
the actual product detectors. The NE604 provides the limiter for
the 602 used as a quasi-synchronous detector, while the actual
quadrature detector in the 604 normally used for FM detection is
used as a phase detector. The oscillator in the 602 used for
synchronous detection is used for the VCO that locks to the incoming
signal.

> I thought that came from you're comments.

No. I vaguely remember talking about a DISTANT
transmitting antenna which was sending waves to the
receiver in question, and in order to make clear what
"distant" should mean, I said "thousands of wavelengths."

"Energy sucking" does not interact with transmitters
which are thousands of wavelengths distant. It only
"reaches out" within the (fuzzy) boundaries of the
large nearfield region surrounding a very short
antenna.

> I'll have to find
> the particular post. But it doesn't matter If it's 2
> wavelengths, you violate light travelling at the speed of
> light to accomplish it:

Obviously.

What was apparantly missed in the long exchange was the fact
that the XXXXX effect (sucking? cancelling? whatever.) takes
place entirely in the nearfield region of the receiving
antenna. I made this clear early on, but that was many
days ago, back before the thread started getting
emotional.

> > Are you aware that this whole thread is about two papers

People keep asking, and I've kept posting the citations, so
maybe dejanews is losing messages.

H. Paul and R. Fischer "Light Absorbtion by a dipole",
SOV. PHYS. USP., 26(10) Oct. 1983 pp 923-926

C. F. Bohren, "How can a particle absorb more than the light
incident on it?", Am J Phys, 51 #4, pp323 Apr 1983

Tonight I'll type in the abstracts.

Last night I drew some diagrams of a related phenomenon in
an attempt to rebut some of the objections people have
made. If this circuit-effect is wrong, then "energy
sucking" is wrong:

http://www.amasci.com/tesla/nearfld1.html

But if the above effect is real, then several of the
arguments against "energy sucking" are exposed as
incorrect.

> I cant believe

> do. Are you also aware that even prl comes out weekly
> and is unlikely that every or even a substantial fraction
> of what is published there is intended to do anything
> but propose further investigation?

Certainly. I've heard it said that only half the papers
in the top journals are wrong. :) I don't claim that
these papers are right because they are in physics journals,
I only claim that the basic ideas didn't come from a
PURE crackpot source, myself. Instead I got them from a
slightly more reputable place.

> You are claiming that
> something which, as you describe it, requires a rewrite
> of modern physics and the papers describing the effect
> has generated no interest?

I think it has generated no interest because it requires no
such rewrite. It is just a new interpretation
of known EM phenomena. In antenna theory, it's apparently
contained within the "effective area" concept pertaining
to short antennas. It's best application is in explaining
how small bits of matter can strongly interact with EM
radiation, even when the physical dimensions of the bits
of matter are *far* smaller than one wavelength at the
frequency in question.

> Have you checked to see if there exist responses? Or
> followups?

No. It didn't occur to me. I shall do so. I'd like
to see them myself.

> And just as a reminder, I am unlikely
> to consider anything at keelynet a physics article.

Nope, this has nothing to do with Keelynet. The only
"fringe" component is this:

N. Tesla claimed to be able to light a bank of light bulbs
tens of KM from his transmitter. It is commonly argued
that such a thing is impossible, since an enormous array
of receiving antennas would be needed. However, if
the "effective area" of electrically short antennas can be
greatly increased by adding a resonator, and if Tesla was
using wavelengths where the nearfield region was physically
very large, then maybe a fairly small receiving tower or
a balloon-bourn vertical wire could have accomplished the
trick.

> The same sorts of claims have been made for the cfa,

> and despite the fact that the thesis that contained it was
> accepted in partial fulfillment for a degree. If this happens
> to be related to the cfa, I'll state right here that it's
> wrong.

Not related to the CFA. However, in learning about
"energy sucking", I realized that the CFA stuff is
misguided. If electrically short antennas can serve as
efficient transmitters through use of appropriate
matching networks, then we don't need any "crossed
fields" to explain why a relatively small metal cylinder
can behave like an immense AM radio tower.

This is a Networks International Corporation hermetically sealed commercial quality 30 mHz low pass filter. Both input and output connections are 50 ohms BNC. The second picture shows the filter roll-off above 30 mHz. Each horizontal line represents 10 dB of attenuation. This is a great filter to keep unwanted rf out of your shortwave receiver front end.

This knob has a scale of 0-100 and a 10 to 1 gear reduction. It takes 5 turns of the knob to produce 1/2 turn of the output shaft and dial indicator. It connects to a 1/4 inch diameter shaft. It is NOS (new old stock) and excellent condition.

Hello Floetay,
I have a calculator mady by Canon in 1970. The type is Palmtronic LE-10.
The built in battery is defective but it still works when attached to
the power supply / charger.
It is in pretty good shape. Are you interested?

In case you are thinking about it, and haven't read the many articles, here is what i found (in a nut shell).

As they come off the shelf, they have a secondary voltage of about 2700 vac. They will draw about 10 amps unloaded! Here is what to do about it. Locate the magnetic shunts (blocks or plates of silicon steel) between the primary and secondary. Use a drift to knock them out. The tranny will now behave more normally, but for most folks you will want to remove some of the wire on the secondary, as the output voltage will be far to high for most uses. I am running an 8930 at 600 watts input, and 400 watts output, and my tranny barely even gets warm.

Can you explain this? I understand the lagrangian is a function describing the stored vs kinetic energy? Psi is the phase? What is i and mu?

> If an electron is to be free to reference things (like fields) from it's
> perspective (gauge invariance) then you would argue that the phase of

That makes sense, the absolute value |/Psi|^2 is the amplitude or energy of the particle?

> In other words,
> replacing \Psi by exp(i\phi)\Psi doesn't change the physics. If
> you do that above:

What is exp(i\phi)\Psi ? Is this the complex (exponential) expression of a sinusoid?

> We want each electron to
> be able to choose it's phase independently and be able to use the
> same equation to describe the world,

The meaning of gauge invariance?

> And A transforms as A -> A + (1/q) \partial (\phi)
>
> You'll note the similarity between this and the classical
> gauge transformation.

If I knew the classical gauge transformation, something like the Lorentz?

> This works out okay
> because no one has detected a photon mass. You can get a
> mass, but it requires a new particle - the higgs.

Maybe this could be because its conserved during emission and absorption?
I've heard the higgs mentioned before. Was it ever detected?

I have this silly notion that the magnetic vector potential is a
longitudinal force, the compression of a string mass along the time axis,
and the electric scalar potential is the instantaneous density of mass-time.
Mass-time is equivalent to charge. This combination of 1d longitudinal waves
with 3d transverse waves leads to soliton-photons. In which case mass is a
bit of charge density that travels along with, trapping energy and
stabilizing the soliton.

If photons have mass it would seem that it could be detected similar to the
way acoustic radiation pressure is detected, the B(3) magnetic field is
similar to the air/fluid stream that is created by sound?

> In GWS (the term used in the paper for weinberg salaam), they
> were unitinting the weak and E&M interaction, but the W+/-
> and Z are MASSIVE, not MASSLESS. I'm not going to even attempt
> to do this in any detail, since a book would do a better job

And I'm afraid its a waste to throw a lot of equations at me I don't get. A
lot of engineers and technicians at my level look for understanding of
relationship. Of course equations convey these, but all to often I find the
equation forms too obscure to understand unless I get a lot of exposure. I
was relieved to read that 90% of physicists only understand 10% of what
their colleagues write!

> However, the salient features are
> that you get 4 massless fields from gauge invariance.

The fields are the EM vector and scalar potentials, and the potentials
carried by the W and Z?

Thanks for your patience!

Scott

The last item that I recall that "didn't need a rewrite" and
would have produced less controversy if true, was the cold
fusion fiasco. Despite the fact that not a single person I
knew gave it a hope (though one of those persons got a _lot_
of equipment for letting an experiment sit unattended for
a real long time since no data ever showed up), companies
were willing to simply throw away a million here a million
there on the infinitessimal possibility they would get
some of the rights to something they had nothing to
do with. In that context, I would have expected an effect
that has more severe consequences to spark a bit more
interest.

> how small bits of matter can strongly interact with EM
> radiation, even when the physical dimensions of the bits
> of matter are *far* smaller than one wavelength at the
> frequency in question.

The wavelength applied to a photon is nothing but an
artifact of it's probability distributionn. The E&M
interaction between a photon and a charge is not
spread out. It makes zero difference what the wavelength
is - that wavelength is NOT the size of the photon
it's the size of the space surrounding a point
some distance away from the source where the photon
is most likely to be found. It may be useful to picture
a photon as being that size, because a cross section
is also a statistical process and has units of area,
but attaching a physical size to a photon is totally
unphysical. Read what I posted to someone that asked.
If the photon has a size, then the photon has to
retain the geometry as it moves and hence has
a finite spacial extent from its own viewpoint.
BUT, the photon has no restframe (viewpoint) because
it moves at c. Any size would be contracted to 0

if you try to endow it with one. What is the separation
distance of two points that move past you at c?

> very large, then maybe a fairly small receiving tower or
> a balloon-bourn vertical wire could have accomplished the
> trick.
>

Since I am not familiar with the particulars of the claim,
I really cant say much about the likelyhood of whether there
is merit to the claim or whether the antenna has any bearing
on it.

> fields" to explain why a relatively small metal cylinder
> can behave like an immense AM radio tower.
>

What's misguided is the concept of the crossed-field. Every
time I think of that concept, I come up with another physical
law that it violates - and considering how many that is,
it amazes me the concept got past the ee department in whatever
uniiversity it was and is still being used to promote it the
antenna with a straignt face. (I have no data on whether it
works well or not, but it doesn't work in the way the propaganda
sheets want people to fall for). I suspect that, if the people
that invented it actually understand what they're saying, then
they've probably maintained their insistance because the
patent ($$$) depends on it.

>
>The reason you give above ("we want each electron to ...") would
>indicate that it's just for our pleasure. But it is mysterious why
>nature seems to have a preference for gauge theories.
>

Well, at some point, it will be impossible to know just how one
or several conditions were chosen by nature. (At least I'm hard pressed
to belive that at least one parameter is free and that the best explanation
is that any other value but the measured or calculated value soesn't work).

So, what is the most general and reasonable restrictions you can
put on natural phenomena? In my opinion, it's the statement from
one of the postulates of special relativity that laws of phyisics
are the same in every inertial frame. Once you have that, which is
really pretty liberal as far imposing a personal view on what is
aesthetic, then gauge invariance follows from noether's theorem. The
fact that qed works better than any other theory ever to grace the
world, leads me to belive there is some merit to thinking in terms
of symmetries for all physical laws. Sure. None of HAS to be correct,
but much as some people would like to believe otherwise, aesthetics
probably has more to do with the theoretical insight of every great
physical theory than anything else. Intuition is nothing more than
having a good sense of aesthetics. Nature has a preference for gauge
theories because they avoid specifying preferences at all. Even when
the symmetry is broken, it's only hidden. (yes, that sounds cliche,
but I couldn't think of a more original way to state it).

Removing the shunt will mean the secondary can supply current with
less droop, but i doubt it will reduce the unloaded primary magnetizing
current.

To be honest, Weinberg does discuss this in the introduction to
chapter 8, and one argument he gives (speculative as it may be)
is that it would follow from superstring theory.

Of course, there is momentarily no evidence that superstring
theory is correct.

>> *Psi = conjugate
>
>Can you explain this? I understand the lagrangian is a function describing
>the stored vs kinetic energy? Psi is the phase? What is i and mu?
>

\Psi is the electron (or any other charged fermion). \mu (and \nu)
are indices over the coordinates t,x,y,z so they run from 0 - 3.
x0 <-> t, x1 <-> x, x2 <-> y, x3 <-> z., i is the usual -1^{1/2}

The \gamma matrices are the matrices you get from the dirac equation
that are usually represented by taking the three \alpha matrices and
the \beta matrix:
- - - -
\alpha = | 0 \sigma | \beta = | I 0 |
| \sigma 0 | | 0 -I |
- - - _

\sigma = pauli matrices, I = 2x2 identity,
0 = zero where nothing else is.

and multiplying them out \gamma^{\mu} = (\beta, \beta\alpha) so that the
dirac equation appears in covariant form. (and all of that comes from
solving E = p + m, with the quantum mechanical substitutions for E,p)

>That makes sense, the absolute value |/Psi|^2 is the amplitude or energy of
>the particle?
>
No. It's the usual probability flux. You need to obtain a physical property
from an observable: <\Psi|eE\vec(r)|Psi>, for example.

>What is exp(i\phi)\Psi ? Is this the complex (exponential) expression of a
>sinusoid?

\phi is a phase angle. Multplying the wave function by a phase angle is no different than letting:

sin(X) -> sin(x + \phi(x)) where in this case the angle depends upon x rather than a constant.

>The meaning of gauge invariance?
>
It's synoymous with phase invariance. It's like spherical symmetry in geometry, all points are equivalent, so rotating a sphere throught any angle cant change anything.

>I've heard the higgs mentioned before. Was it ever detected?
>
The higgs for this symmetry breaking has not been detected. One spectactular problem is that the higgs mechanism puts absolutely no constraint on the higgs. According to "those in the know", I think the upper limit from some general consistency requirements puts it somewhat above the t-quark. The theory also doesnt forbid it from being a composite particle. In superconductors, the higgs is the cooper pair.

>with 3d transverse waves leads to soliton-photons. In which case mass is a
>bit of charge density that travels along with, trapping energy and
>stabilizing the soliton.
>
The problem with it being a soliton is that the soliton is the wrong way to optimize a wavepacket to give minimum uncertainties in the fourier tranform pairs, like \Delta p \Delta x . The optimal wavepacket is a gaussian.

>If photons have mass it would seem that it could be detected similar to the
>way acoustic radiation pressure is detected, the B(3) magnetic field is
>similar to the air/fluid stream that is created by sound?
>
Since the limit that previously posted for the photon mass was < 10^-46 gm, it's unlikely it will be measure directly. There is a discussion of such measurements in the 1st chapter of Jackson, 2ed.

>was relieved to read that 90% of physicists only understand 10% of what

But you asked. I tried to avoid it, but at some point, you either have to believe the answer or work throught the grundgy details yourself. You didn't want to just buy the result, so you got some details to start with.

>> However, the salient features are
>> that you get 4 massless fields from gauge invariance.
>
>The fields are the EM vector and scalar potentials, and the potentials
>carried by the W and Z?
>

The fields are the photon which carries the E&M interaction, and the
W++/- and Z which mediate the weak nuclear force that casues beta decay.
The theory predicts a lot more than the massless photon. The symmetry
in the W+/- and Z has (well verified) consequences in beta decay.

I'm hoping someone out there can help me with a scan or photocopy of an article on the Wilderness Radio multiband CW QRP kit called the 'Sierra', which apparently has appeared in the last 3 editions of the ARRL Handbook and also in June 1996 QST magazine. Please reply direct to my address below and I will obviously reimburse any costs involved.

Many thanks in advance.

John.

Check out any of the ARRL handbooks prior to about 1965 or so. For a radio hobbyist (as opposed to a professional engineer) they are probably your best source of tube design information. There are usually several available on eBay.

Apparently, with the shunts in place, the primary is operating with
a nearly saturated core, and the unloaded current is high, with a
poor power factor. One Triad transformer that I ran tests on, showed
over 10 amps of unloaded current, and dropped to less than 1 amp with
the shunts removed. Others showed a similar trend. And amazingly, after
taking out the shunts, the secondary voltage only increased about 3-5
percent across the samples I converted.

What if the fluid-like nature of the vacuum is not impressed by the fourier transform? I mean if it is nonlinear, perhaps another basis function could better describe it, especialy those available with wavelets? Aren't there windowing problems with the fourier transform to deal with when using it to describe a composite impulse?

[Article crossposted from sci.physics.electromag]
[Author was Science Hobbyist]
[Posted on Wed, 15 Mar 2000 01:49:31 GMT]

I've put together a little website about the simple ideas
which underlie the "energy sucking" concept. These DO
NOT involve EM travelling waves and distant transmitters,
but instead focus only upon simple circuits. If we
can't come to agreement about this simple circuit, then
there's no point in arguing about "energy sucking"
antennas and waves in space.

Simple capacitive "antennas"
http://www.amasci.com/tesla/nearfld1.html

On the other hand, if the above circuit proves to have
a fundamental flaw, then "energy sucking antennas"
probably has the same flaw. The clearer I can make
the ideas, the more robust they become, but also the
easier it is to find any big holes.

2055. diode mixer questions

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-15 00:00:00 UTC
From: Fred <fdecker@compuserve.com>
Message-ID: <8aoh6s$53l$1@ssauraab-i-1.production.compuserve.com>
Source record: 62544
Cross-posted to: alt.engineering.electrical,rec.radio.amateur.homebrew,sci.electronics.basics

I am trying to learn how diode mixer circuits work, they are so simple, but I don't understand design issues about component values.

First. I have seen usually seen what looks like the input and the mix being fed into a diode that is fed to ground through a resistor. How do you choose the cap value? Are they just coupling capacitors?

What about impedance at RF levels? I will be in the 146mHz range and wondered about keeping a 50 ohm impedance to the output and do I need a high or 50 ohm impedance on the input? Does the diode have an impedance I should calculate?

Also, I have seen the resistor replaced by a choke, what's going on with that? How do I determine the value of the resistor or choke necessary? And why on some circuits is the output cap not used, especially if the choke is in there instead of the resistor?

Does it matter if the RF grounds are tied to the DC ground or do they have to be separate? I've seen it both ways. :(

In the circuit below I have seen the two resistors as 1k - 2.2k and the caps 100pf - 470pf. Can anyone explain this circuit to me? Thanks.

Source record: 62395

David,
I've been using a homebrew dummy load for about 15 years. This consists of 20 1KOhm 2W carbon resistors soldered, with zero length leads, between two bits of PCB material, one soldered to the can lid and the other to the center conductor of the coax connector. the resistors are immersed in mineral oil. This will take 150 watts happily for as long as you like, and mine still reads within one or two percent of it's initial value. For higher powers you will need bigger resistors, or more of them. 200 10 KOhms maybe? It wouldn't be that big and should take 1KW for short periods in oil.

If you can get the big 50 Ohm job then you are in business, but they do tend to be rather expensive.

Quoting directly from your web site:

"To adjust R1 for maximum energy (matched impedance), we set R1 equal to the series reactance created by
the voltage divider, which is 1/(2*pi*f*100pF) or approximately 3.2K ohms."

This statement reflects a complete misunderstanding of impedance matching. The impedance of the capacitor is 0 -j3200. The impedance of the resistor is 3200 -j0 (or 3200 +j0, if you prefer). The _magnitudes_ of the impedance are the same in both cases, but one is totally reactive; the other is totally resistive. To get maximum power transfer, you need a _conjugate_ match, which requires an impedance of 0 +j3200 in series with the capacitor. It just happens that this is the condition for resonance. Since the real part of the "source" impedance is zero, maximum power transfer also requires that the load resistor be made equal to zero. Unfortunately, it takes infinite current to produce any power dissipation in a zero ohm resistor, but that's a minor detail.

There is nothing new or magic about small antennas containing high Q matching (or resonating, if you prefer) circuits. It's simply a game of making the antenna and its matching circuit as efficient as possible in order to transfer the maximum energy out of a transmitter or into a receiver, and people have been playing that game since the early days of radio. Resonance and impedance matching go hand in hand, and high Q is necessary to minimize losses in the antenna/matching network combination.

Please go and build the best energy sucking antenna you can, and then tell us if there is anything about its performance that is not consistent with long-established circuit and antenna theories.

What sort of resistors did you use for the 100:1 tap - ordinary
leaded types or surface mount?

I've been planning to put a 1000:1 ratio tap into one of my dummy
loads, basically turning the thing into a 60 dB pi-type attenuator.
I have been thinking of using surface-mount resistors (not likely to
be inductive), but don't know whether I need to put the resistor
network itself inside a shield to prevent RF pickup that bypasses
the resistors.

dvmcguire@mindspring.com writes:
>Does anyone have some designs for building a homebrew "cantenna"?

Take a look in older ARRL handbooks. The 1990 one has designs for two different ones. One uses a plain cylindrical ground around the load resistor and is good for use up to about 144 MHz. It will handle 1500 W for 10 min.

The other uses a tapered matching section into the resistor and a tapered ground around the resistor, and is usable up to 1.3 GHz, handling 1000 W for 5 min.

These are on pages 34-22 to 34-29 in the 1990 ARRL Handbook. They are probably in Handbooks from other nearby years as well.

Anthropomorphic principle. Nature is the way it is because if it were different,
we couldn't be here to observe it. In other words, we can imagine a universe
with different laws, but we couldn't live in it because it couldn't support human
life.

Let me TRY to cut through the misunderstandings here.
I think I understand your objections for the most part,
and I will reply, but I'm *NOT* yet clear on WHICH things
you're objecting to.

I claim that by adding a tuned circuit to a short
dipole antenna, I can make a load resistor dissipate
more energy than if the tuned circuit was not present.
You DON'T object to this, right? You say that it's merely
a matter of impedance matching. Or have I misunderstood?

Are you only objecting to my weird "energy sucking"
language? Or are you also objecting to my assertion that
a load resistor can run hotter if a tuned circuit
is part of a short antenna?

Also, do you accept that the effect depicted on
http://www.amasci.com/tesla/nearfld1.html is real?

Jack,

http://www.qsl.net/pa3gco/bluecap/blue.html has some great conversion details on a old Blue Cap LNB, this is for TX though.....For RX I use a standard Astra LNB and have adjusted the size of the puck (White small ceramic tablet looking thing) by sticking a small amount of glass onto the puck.

I found that glass or another ceramic material on the puck drops the frequency (In my case 500MHz) and a metallic material will increase the frequency. I spent ages cutting and grinding glass to fit to the puck, but in the end I managed to get me LNB down to 10.450 GHz.

Hope this helps......

> It seems to me what you've discovered there is simply an example of
> conjugate matching.

Exactly.

I'm having trouble with this discussion because some
people apparantly are saying that the effect shown on
http://www.amasci.com/tesla/nearfld1.html is impossible
and does not exist. At least I THINK that's what they
are saying. I'm not sure. Before I continue going on
about "energy-sucking antennas", I want to hear whether
everyone accepts that this capacitor effect is normal
and boring and well-known, and certainly doesn't
violate any fundamental physics.

The next stage of my arguement is to put the little
capacitor-antennas in empty space and present them
with waves from a distant radio transmitter. The same
effect should arise: the antenna with the tuned circuit
should do better at heating its resistor than the antenna
without the tuned circuit.

(Newcomers please note that the capacitor-antenna is
electrically small; its size is << than a wavelength.)

Why not try it and see?

Converted Ku-band LNBs are a staple of wideband 10 GHz operation.
Depending on the exact frequency they will either use an image
response in our band, or a custom DRO puck, or one with stuff
glued to it to change the frequency. They work well.

10 mW = +10 dBm
300 mW = +24.8 dBm

Gain needed: 14.8 dB.

I suppose that you could easily perform this amplification with two gain stages, conservatively speaking. Others may argue that only one gain stage is needed.
More than a few parts would be an input matching network, the
first gain stage with bias components, coupling to the second stage, bias, and
an output matching network. You also have to check the regulations for maximum power, and the maximum spurs allowed, which means that you may need an output lowpass or bandpass filter.
But perhaps not at this low power level.
These parts are relatively small, however, your second (output) stage will need heat sinking
if you are operating class A.
Sounds like a fun project. Best of luck.

89-98

Jan-Martin,

There are online indices for 1989 to 1998 issues at:

http://oak.oakland.edu/pub/hamradio/arrl/infoserv/qst/

I don't know of any for earlier issues.

If you have a topic in mind, try looking at:

http://oak.oakland.edu/pub/hamradio/arrl/infoserv/bibliog/

and you might find that the subject is in one of your issues.

> I think your circuit model is too simplistic.

It was meant to be. I'm making it very simple so that
the flaws become easily seen (or their lack becomes
obvious).

The tuned circuit in http://www.amasci.com/tesla/nearfld1.html
causes more energy to be available to the load resistor.
It's not simple a bandpass filter; there are some
energy effects here.

> In the no-inductor case,
> assume Rl is infinite; now reduce C1 (leave the C1 plates the same
> distance apart, but just reduce their area). Your simple circuit model
> predicts that the voltage across C1 approaches Vgen as the plates are
> made smaller, which is clearly not the case.

Not correct, because the parasitic coupling capacitances
will also shrink as you reduce the area of the C1 plates,
leaving the 100:1 division ratio about the same.

However, note that the whole point is to compare the
two circuits. Does the tuned circuit allow R2 to
receive more energy than R1? Unless there is
something fundamentally flawed about my reasoning,
the answer is yes. If I've made small errors which
reduce the 100:1 power ratio, the answer is still yes,
as long as that ratio is significantly above 1:1.

Also, this isn't a discussion of the practical
problems. Several people have insisted that this
cannot work even in theory!

> And why argue? Just build one and try it.

Good point, but a simple schematic on a website can
clarify many issues, while a real-world device sitting on
my lab bench is inaccessable to folks on newsgroups.
And besides, if I build it and it generally operates

as I say, then those who have something against
these sorts of ideas will just insist that I've made
measurement errors, or that I'm perpetrating a hoax
or something. By focusing discussion on a schematic,
many hidden flaws can be exposed, and onlookers can
reason it out for themselves.

"Boring and well known" is the right end of the spectrum,
maybe "boring" is a bit too strong. A small antenna always
looks like a source with resistance and reactance (R+jX).
X is <0 for dipole-type antennas and >0 for loop types. As
you wind the frequency down, R decreases and abs(X)
increases so that when you conjugate-match the source
impedance (thus forming a tuned circuit), the Q goes up and
the bandwidth goes down.
For dipole-type (electric) antennas, R varies as f^2 and X
varies as 1/f (like a fixed capacitance). For loops (magnetic),
R varies as f^4 and X varies directly with f like a fixed
inductance. In each case Q (roughly X/R) varies as 1/f^3 so
the bandwidth f/Q varies as f^4.
In practice, the bandwidth can be maintained by adding extra
resistance which reduces Q. This produces losses such that
antenna gain times bandwidth remains roughly constant. An
AM radio's loopstick is a good example - its loss resistance
may reduce the available signal by over 60dB but its
bandwidth is adequate and it is a good antenna for its purpose.
Alan

NO. What everyone is trying to tell you is that there is
nothing at all strange about having the power transfer
change as a function of impedance. You just wont believe
that there should be a difference if it were not for the
"energy sucking" bit. Your circuits are NOT equivalent
by any stretch of the imagination.

This is part of your misunderstanding. A filter of ANY sort
is a filter ONLY because of "energy effects". You just cannot
filter without it being an "ebergy effect". Where does the
power go? Think VSWR.

Could we just cut to the chase here? Is there anything new in expecting
to match the load to the antenna to maximize power in the load? That's
still pretty boring to me, I'm afraid. Now if you can find an
efficient way to match an antenna which can be represented by
0.01-j10000 ohms to a load (without using superconducing inductors),
THAT will get me interested. Using such an antenna (a typical very
short dipole [about 0.044 radians long; about 2 meters long at 1MHz] or
single element fed against a ground plane) as a transmitting antenna
would still likely have problems, even with a high efficiency matching
network, because even 1 watt will cause some rather high fields: the
feedpoint will see 100 amps and 1 megavolt in that example.

Cheers,
Tom

tnx, I have now studied the circuit diagram. When building the
complete OH2GF circuit you need a phase detector, and it seems easy to
use the balanced modulator inside NE604, but if you only need a
quasi-synchronous detector it seems no reason for not using this
stage.

One problem with the complete circuit is that 455khz VCO may spread
signal back into the receiver and cause more or less interference. The
amount of problem depends on which receiver you use, but don't imagine
adding this circuit to a BC-radio.

LA7MI solved this problem 20 years ago using 910kHz VCO for his add-on
used with FRG-7. I wished to copy it, but had problems because he used
only discrete components - had to invert connections to a ringmixer if
it didn't lock, but when loop gain is low it may or may not lock, so I
reversed the connections some times and resigned. It would be an idea
to improve the old circuit using modern devices, but I do not really
listen to AM broadcast much any more, Radio Luxembourg is closed
several years ago but I don't know about BBC Radio 1.....

If some interest, I could look for LA7MI's circuit and scan it.

yes, a very easy approach is Motorola MHW720 power module, but you may
find other surplus modules from mobile telephones on 440-470MHz.
The MHW720 usually gives full RF output on 432 with 10mW or so.

I plan to use MHW720 on some of my beacons, I have built 15 totally
over the years for 144, 432, 1296, 2320MHz, believe I participated in
two 10m beacon projects, too.

For 70cm it is easy to mount, you just use tinned iron plate (those
are very popular in Germany and around) under the power module, and
make short groundconnections to this plate, it must also go under the
power module so it has good ground, but remember cooling pasta under
the power module and between the plate and cooling

UHF Unterlage shows some printed circuit boards which goes with
M57762 for 23cm, but it seems not important for 2m and 7c0m

It also exists some smaller power modules, DF9IC seems to like such in
his packet radio transmitters, but I have no experience with using
such

You can build a bi-band loop antenna; a 1 wavelength for 80 and 1/2
wavelength for 160 or a smaller one, 1 wavelength for 40 m and 1/2
wavwlength for 80.
You can look at The ARRL Antenna Book. It's a very good source of info.

You said that you found errors on
http://www.amasci.com/tesla/nearfld1.html

You haven't yet said what they are.

Therefore, I don't know how to go forward with any
kind of discussion, because I cannot see the errors
on that website.

For the moment, I'm abandoning the "energy sucking" debate
and trying to get some very simple questions answered:

1. Is the stuff on that webpage correct?

2. And if not, then where are the big flaws?

What is wrong with the math or conclusions on
http://www.amasci.com/tesla/nearfld1.html ?

You've said that there are errors on that website.
What are they? I honestly want to know.

I'm holding off on discussing my ideas, and instead looking
for something very simple: major errors on the website:

http://www.amasci.com/tesla/nearfld1.html

If they are there, I cannot see them, but perhaps
somebody here will see things I miss.

That increase in power is one part of an ongoing debate.
Some of the people in the debate SEEM to be saying that
the stuff on http://www.amasci.com/tesla/nearfld1.html
violates fundamental physics principles. Others SEEM
to be saying that this stuff is normal and conventional.

I'm hoping that anyone who objects to the stuff on
that website will help cut through the "noise" by
clearly voicing their objections (and perhaps by pointing
out where the flaws lie.)

Scientists of high integrity will do exactly this. Feynman
discusses "scientific integrity" in the whole second half
of his article called "Cargo-cult Science." He calls it
"a principle of scientific thought that corresponds to a
kind of utter honesty--a kind of leaning over backwards."
This utter honesty requires that we admit our mistakes
publicly as soon as we discover them.

In a scientific discussion among people of integrity, typical
"debating tactics" used on newsgroups become abhorrant.

For example, if it looks like I'm about to be proved wrong
in public, and therefore I start sowing confusion, or
suddenly attacking unimportant details, or mysteriously
changing the subject, or suddenly becoming angry in order
to deflect attention, then my behavior shows that "winning"
and "losing" is far more important to me than getting at the
truth. My behavior might be normal for newsgroup debates,
but people of integrity do not do such things.

Perhaps many scientists lack integrity. Perhaps "being
right" or "avoiding public embarassment" is more important
to them than insights and truth. Perhaps they would rather
preserve their egos by hiding their mistakes, as opposed to
shining a bright light on their mistakes so that others
will not be misled. That doesn't mean that scientific
integrity doesn't exist. It just means that it is rare.

CARGO CULT SCIENCE
http://www.physics.brocku.ca/etc/cargo_cult_science.html

> It
> never happens, at least not in public.

It certainly does! It's happening right now. One major
reason I'm pursuing this "energy sucking" stuff on
sci.physics.electromag is to give others the opportunity

to show me my horrible errors. When that occurs, you'll know it, because I will clearly state that the light has dawned for me, and that the other side was right all along. (No, it has not occurred yet, since I see good counter-arguments to MOST of the objections I've heard so far.)

> It's not up to them
> to resolve their differences - the test of time is the one
> that counts.

Very sad that this is often true. Max Planck says it thus:

"A new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die and a new generation grows up that is familiar with it." - M. Planck

I'm amazed to find that this also applies to simple little concepts as well as to "new scientific truths." If people are introduced to an idea which they haven't encountered before, often they will adopt a stance of heavily-defended disbelief, and would rather fight it to the death than to admit that their knowledge is incomplete. This is particularly a problem in the sciences, and with those who fancy themselves to be experts. Science attracts people who cannot stand to be proved wrong. (I should know, since that's why I was attracted to it myself!) To counteract this tendency, it is better to be humble like Einstein, and to consider oneself to be a mere student, rather than to be certain of our great expertise and therefore to become increasingly immune to learning anything new.

Another good article besides "cargo cult" is this one:

Someone recently gave me a few "73 Amateur Radio" issues for 1990,
and Mike Bryce's (WB8VGE) QRP column in the October issue starts out:

"Last month I described one of my personal favorites, a VFO...."

Unfortunately Murphy struck, and I did NOT receive the September issue!

If anyone has built that particular VFO, I'd appreciate hearing
how it worked, how you like(d) it, etc.

Or, if anyone has that particular issue, I'd like to receive a copy
of the QRP column for that month. (So I don't get a zillion copies,
it might be best if you'd email me first....)

See what value of non-inductive power resistors that you can get your hands on. Wirewounds are not good.
50 ohms, 100 ohms, whatever. Then work out a series parallel combination.
For example, solder them in a parallel group of five 50 ohms to make 10 ohms. Then put 5 of these
bunches in series, so they total 50 ohms.
Buy a new virgin paint can from a hardware store. Drill a hole in the top, and mount the appropriate
bulk head connector. Mount your resistor array to the connector, so everything is hanging from the lid.
Fill up the can with NON-FLAMMABLE, non-conductive oil.
You may wish to build an adapter which contains a coupler, or attenuator and perhaps a diode detector for frequency
measurement. I did this externally, using a Tee adapter.
One more thing, try to keep the can level.
The oil has a tendency to leach out of the lid or connector area over the years.
This kind of dummy load is one of those things that any resourceful ham can build.
Good luck,
Al

For just a moment, forget you ever saw C1 and R1. Take a look at the tuned circuit.

If R2 were made infinite, then the voltage across C2 should increase to become equal to the voltage applied to the large plates.

With no voltage across either Ca, then there would be no current through either Ca and no power could be transferred from the generator to the infinite valued R2.

If R2 were made zero Ohms, there would be no voltage across C2 and no power could be transferred to the zero valued R2.

For some particular value of R2 in between zero and infinity, a maximum amount of energy is transferred from the generator to R2.

That's all obvious to me and probably to you as well. There is a single particular value for R2 that maximizes the power transferred to it.

Removing L1 changes the particular value of R2 that results in maximum power being transferred. The "interesting" thing is not that adding an inductor improves the power by 100 times, it's the fact that removing the inductor *reduces* the maximum available power by 100 times.

In the case of EM waves, free space, a vacuum, has an impedance of around 370 Ohms, IIRC. Any resistor inserted in an EM field other than one with a value of 370 Ohms intercepts less power than one matched to the impedance of free space.

Jim

> ohms."
>
> This statement reflects a complete misunderstanding of impedance
> matching.

No, it means that I should change the wording because
you're right, "matched impedance" does not describe
what I'm trying to do by adjusting R1. I'm trying to
find the BEST RESISTANCE VALUE for R1: the value that
gives the highest power that a purely resistive load can
attain in this situation. I understood that Pd max
for a resistor in a simple series RC circuit occurs
when R1 = 1/(wC). Maybe this is wrong.
Let's see...

If I calculate Pd for R1, and seeing that Ca << C1, I
get:

Pd = 100^2 * R1 / (R1^2 * 1/(w^2 * C1^2))
(where w = 2*pi*F, as usual)

and if I try plugging in various values, I find that 3.2K
indeed gives the maximum Pd. If this is wrong, please
tell me where the error is. It would also help if
you could say what the value for R1 should be, rather
than the 3.2K I calculate.

> The impedance of the capacitor is 0 -j3200. The impedance of

> reactive; the other is totally resistive. To get maximum power
transfer,
> you need a _conjugate_ match, which requires an impedance of 0 +j3200
> in series with the capacitor.

Correct, if "impedance matching" was my goal with R1. But
my intent with R1 is to find the best resistance value,
not the matched impedance value, and then to compare it
with an identical "antenna" which has an added inductor
to create resonance. I'll go fix my incorrect "impedance
matching" wording on the webpage.

> It just happens that this is the condition
> for resonance. Since the real part of the "source" impedance is zero,
> maximum power transfer also requires that the load resistor be made
> equal to zero.

Oops! Ooops! max power at ZERO ohms?

> Unfortunately, it takes infinite current to produce any
> power dissipation in a zero ohm resistor, but that's a
> minor detail.

This is wrong. Power goes DOWN if I reduce R2
below 320K. If I reduce the value of R2, then the
voltage across it becomes less, and the current climbs
towards a maximum value set by Ca/2 being in series with
with 100V. When R2 reaches 0 ohms, then the current
through R2 reaches 100/(wCa/2), but a finite current
through a zero ohm resistor gives zero power. I
calculate the power in R2 to be:

Pd = V^2 * R2 / (R2^2 * 1/(w^2 * (Ca/2)^2))

...which gives ~320K at max Pd, the same result
I find if I set R2 = 1/w(Ca/2) Please feel free to
verify for yourself that I'm not making big mistakes.

> There is nothing new or magic about small antennas containing
> high Q matching (or resonating, if you prefer) circuits.

So you agree that the calculated power ratio of 100:1
between the two antennas on the webpage is correct?

Do you also agree that the e-field near the C2 plates
is far stronger than the e-field near the plates of C1?
Or am I mistaken about this strong e-field?

> Please go and build the best energy sucking antenna you can, and then
> tell us if there is anything about its performance that is not
> consistent with long-established circuit and antenna theories.

I'll get to that later, after I'm sure that there are no fatal flaws in http://www.amasci.com/tesla/nearfld1.html, and I hear some agreement about what the "long established theories" actually predict. Do they say something radically different than what I'm saying on the webpage?

The stuff on that website is DEAD SIMPLE. If the 100:1 difference in energy is wrong, and if the large voltage and e-field associated with the C2 plates is wrong, then somebody who knows simple AC circuitry should be able to point out the glaring errors.

This is just a thought. Just simply mail order the MFJ dry dummy load. It won't spill, it is lighter and takes up less room, and it has an excellent VSWR acceptance at least up to 450 mhz. I have owned several cantennas, and I like the MFJ dry load much better. Also, I built a 100:1 voltage tap into mine to drive my tek 2215 scope for monitoring rigs under repair.

I'll put this here because it might also be useful. There's a cumulative
index of Ham Radio magazine at:
Linkname: ham radio magazine index : 1968 - 1990
URL: http://webhome.idirect.com/~griffith/hrindex.htm

I'm not sure if he typed it in himself, or got the information from
elsewhere. A few times I've looked for an article I knew existed,
but couldn't find it. On the other hand, it's broken up into topics,
and I may not have looked in the correct topic.

I have a fuzzy memory of there being some official index for Ham
Radio or perhaps Communications Quarterly, but not only do I not
remember the details, I'm not even sure if I really read about such
a thing. Right now, I'm not going to try a search.

I agree 100% with all of the above. Do you agree with the
actual numbers I came up with? (The resistances, and
the 100:1 difference in power between R1 and R2?)

You could look at it that way, if you intentionally wanted
to make it seem uninteresting. That's no fun, and if
there are any interesting implications to explore, we will
be persuaded to abandon the search before we've seen

them.

And of course you can look at it MY way if you
intentionally want to make it interesting! :)

Another "interesting" thing: when C2 and L1 are tuned to
resonance, the voltage across the small C2 antenna plates
suddenly becomes very large. Unless my calculations are
wrong, it grows to 70 volts instead of 0.7v. And the
e-field in the vicinity of the C2 plates grows as well,
of course. We don't see a large voltage with C1 and R1,
and we don't see a large voltage when the resonant circuit
is tuned away from 500KHz. We don't see large e-fields
in the space between the big metal plates EXCEPT
around the small antenna which is tuned to resonance.

It's ALMOST as if the C2-L2 circuit had become a
signal generator, and was getting energy from somewhere
in order to power itself. Which of course is exactly the
case: some of the energy received by the C2 plates builds
up within the resonant circuit, and rather than finding
only a tiny 0.7v on the plates (as with the C1 R1
antenna,) instead we find a large voltage suddenly
appearing across the small plates when we get the
tuning just right.

> free space.

Right, and we can understand this in terms of resistive
"space cloth," which makes an ideal absorber if it has a
resistance of 377 ohms per square. (I think I got that
value right.) A huge sheet of this "cloth" will absorb EM
radiation without reflecting it. However, what if our
piece of "space cloth" is shaped like a disk, and the
diameter is far smaller than the wavelength being absorbed?
In that case it no longer works very well. The piece of
cloth has started to behave like a tiny aperture, and
EM waves usually refuse to go through holes which are
far smaller than one wavelength.

Is the size of an aperature merely a question of impedance
matching? Changing the resistance of the tiny piece of
"space cloth" doesn't fix the problem when its diameter
is far smaller than 1/4 wavelength. Electrically short
antennas have the same trouble. They act like physically
tiny aperatures, and it doesn't matter what sort of
resistance is placed within the "hole". If the "hole" is

too small, the EM waves cannot go in. Unless...

Looks good from a distance. Haven't got close enough to confirm beyond
doubt though.

> my intent with R1 is to find the best resistance value,

Best meaning that which causes maximum power dissipation.

> not the matched impedance value, and then to compare it

Yeah, but if you add an inductor, the previously computed R1 isn't going to be best any more since you've upset the above formula.

> > It just happens that this is the condition
> > for resonance. Since the real part of the "source" impedance is zero,
> > maximum power transfer also requires that the load resistor be made
> > equal to zero.
>
> Oops! Ooops! max power at ZERO ohms?

Yes perfectly reasonable. If your source impedance is exactly zero ohms resistive, then the max power theorem says that you have to have a 0 ohm load to get max power transfer. Of course this doesn't happen, it's just one end point of the graph of the power transfer equation. Note that it's also the infinite power end since any voltage at all on a zero ohm load gives infinite current and hence infinite power. The other end of the graph says if you have infinite source resistance, you need infinite load resistance to get maximum power. But since that "maximum" power transferred would be zero watts, it really doesn't matter what the load resistance is...

> > Unfortunately, it takes infinite current to produce any
> > power dissipation in a zero ohm resistor, but that's a
> > minor detail.
>
> This is wrong.

No it's not! In fact, it's equivalent to the statement that it takes infinite current to get any voltage drop across a 0 ohm resistor. That statement above is referring to any load in general, not in your circuit. Power in a resistor is current squared times resistance. If R is zero, the ONLY way power is going to be non-zero is if current squared is infinite. And that means infinite current.

Fortunately, it only takes a very small (nearly, but not quite infinitely small) voltage across a 0 ohm resistor to produce this infininte current. Since current is V on R. If R is zero, and V is ANYTHING OTHER THAN zero, then the current must be infinite! So now all we need to do is define a 1microvolt infinite current power supply, and we can dissipate (lots, hell infinite) power in the zero ohm load!!

We're not arguing EM physics now, we're losing sight of ohms law. Better be REAL careful now...

> Power goes DOWN if I reduce R2

In your circuit yes. That's because the Current goes down if you reduce R2.

> below 320K. If I reduce the value of R2, then the

> between the two antennas on the webpage is correct?

Sounds good... As long as it's still not more power than the impinging EM
wave that's hitting the antenna there's nothing wrong with this either.
It just means your putting more of the available power into he load instead
of (re)radiating it into space.

> Do you also agree that the e-field near the C2 plates

I suppose a lot of indexes date from a time when you'd be looking through it by sight, and we're probably lucky that they've made it to electronic form. New material will migrate easily, because it starts out in electronic form, but older items require the effort and time to do the transition.

Every time something exotic comes up here, like the third method of SSB generation or synchronous detection, I am tempted to post extended bibliographies on the topic. The problem is, finding the articles that I remember, and then typing in the details. I never quite get around to it. But in some ways the idea is valid, and probably more useful than looking at old indexes. It would be cross-over magazine lines, which sometimes publishers aren't so happy about doing. And if you've seen an article, an index might help you remember which particular issue it was, but a mere title may not tell you what's in the article. For instance, the Drake SPR-4 receiver had a forward biased diode for it's AM detector, which is somewhat unique and fits this topic of fancier AM detectors, but the only way I know that is from a review in QST (December 1970) that has a schematic of the detector.

And one could actually but in some detail, rather than just have a list of pertinent articles. I have quite a file of articles about grid dip oscillators, and those are just from the magazines I've taken apart, and most of the articles resemble most of the other ones. There isn't much point in listing them all, other than increasing the chances that someone might have an article on building a GDO. But there are some articles that stand out, either because they were particularly informative, or because the design was unique for some reason. Annotating such an bibliography would be useful.

No, we are discussing the circuits on that webpage, and
whether they are wrong or not. If somebody claims that
the power in R1 or R2 goes to infinity when the resistance
value is set to zero, then that claim is wrong. There
is a series impedance between the power supply and
the resistors.

What other guy's circuit? The circuits in question are
at http://www.amasci.com/tesla/nearfld1.html

If R1 or R2 go to zero, no infinite current flows, and
the power in those resistors goes to zero. No other
circuits are being discussed.

Makes no difference in understanding what's going on. I'll accept your
figure.

I'm more concerned with making it "true" than I am with making it
"interesting". Not that it can't be both at the same time in some cases, of
course.

If there are any implications to discover, they will be just as apparent
from a carefully considered examination without the hype as they will be
otherwise. You could have made a similar comparison in which the power ratio
would have been 1,000 to 1. Making it 1,000 instead of 100 doesn't make it any
more interesting if you understand what's going on.

True, the e-field between the large plates is disturbed more when a
resonant device is inserted in the field. That e-field disturbance doesn't mean
that more energy is somehow created though.

> It's ALMOST as if the C2-L2 circuit had become a
> signal generator, and was getting energy from somewhere
> in order to power itself.

That's a leap of faith or wishful thinking. All the energy delivered to the resonant circuit comes from the generator attached to the big plates. Do the math for the current and power supplied by the generator and you will see that the differences in the power supplied to the resonant and non-resonant circuits are supplied by the generator.

Unless you take quantum mechanics into consideration. The smaller you make something, the less sure you can be of its size and/or position in space. It's called the uncertainty principle and it's been thoroughly investigated and "proven".

Single photons presented one at a time to the classical two-slit diffraction experiment *still* produce interference patterns although there are no other photons present to interfere with.

Now *that's* interesting. But it's still not a convincing argument for zero-point energy or a vindication of Tesla's crack-pot schemes.

Jim

The very simple error is your calculation of 320kohms for the
resonant case. The real answer is infinity kohms (ie: bigger
is better).

The resonant network is an inverse impedance transformer, so
the higher the load resistance, the lower the resistance
presented to the source.

At resonance, the source sees a pure resistance. Because the
source is a constant voltage type, then obviously more power
is delivered by minimizing the resistance presented to the
source (hence higher load resistance).

The tradeoff is that the Q gets higher, so bandwidth is lower.
If the center freq=1kHz, and Q=10000, the response time to step
changes in the transmitter level is a time-constant of 3.183s,
ie:quite sluggish.

As you can imagine, the entire system is engulfed in the resonant
condition.

Loop antennas are limited by losses in themselves, and objects near
them.

There is nothing strange or unknown in these resonance effects or
calculations; i use and think about them frequently.

You will realize all these effects are present and used when designing
narrow bandpass filters from lightly coupled hi-Q resonators.

I've had a quick look at the reference and it is correct but I don't see any controversy - it's a restatement of something well known. Tuning a small antenna is just conjugate-matching its source impedance. If the source is R+jX the load has to be R-jX for maximum power transfer. That's general for any circuit.
Alan

I've been given a Heathkit RF Sig Gen IG-102 which is a little worse for wear.

It should have two valves but one is missing and the other is broken. Lots of shards of glass inside the case. From the bits I have been able to piece together I think it may have been an ECC81.

Someone has also been desoldering some of the capacitors inside, whether to try some sort of repair or to rob them for a project I can't say. I don't think any are missing just disconnected at one end. Otherwise all the coils appear to be in place - I should say I can't see where any are missing. The power supply appears OK.

Can anyone let me know what the valves should be and is there a schematic available anywhere on the WEB for this?

Tom.

Hello Ron,

Like so many things, the answer is "it depends". Here's the story:

There are two basic types of power supply filter: Capacitor-input and choke-input - named for the first element after the rectifier. The filter consisting of just a capacitor is the simplest type of capacitor-input filter.

The pros and cons of the two types are listed below. Vrms is the transformer secondary voltage:

Choke input:
- Choke must be at least "critical inductance"
- Output voltage cannot exceed 0.9 Vrms
- Peak rectifier current is only a few times the average, and can be reduced by making choke larger, which also improves filtering
- Good filtering possible with relatively small values of L and C
- Good regulation if a choke with low DC resistance is used
- Good power factor
- Low turn-on surge

Capacitor input:
- No choke needed in some designs
- Output voltage can reach 1.4 Vrms if capacitor is big enough
- Peak rectifier current is several times the average, and is increased by making the input capacitor larger to improve filtering.
- Good filtering requires large C if only C is used
- Good regulation only if large C is used. Poorer regulation than choke input in most cases.
- Poor power factor
- High turn-on surge

In the old days, choke-input ruled supreme for several reasons. The most important reason was the limitations of vacuum and mercury vapor rectifiers - they could not tolerate the large peak-to-average curren ratios of capacitor input filters when used in high power applications. In addition, the only practical capacitors for high power applications were paper-oil type, which are expensive to make and large in size. And a good power factor helped avoid blinking the lights too badly. Finally, in those days the cost of winding chokes and transformers was not that high, so the minimum cost solution involved a lot of iron.

The invention of high voltage silicon rectifiers and "computer grade" electrolytic capacitors changed the game in the 1960s and 1970s. Capacitor values that would have been physically and economically impractical with the old paper-oil caps were possible with strings of the new electrolytics. And cilicon rectifiers of adequate rating could handle the large peak currents. Light blinking and poor power factor were less of a concern as more hams' homes were wired for 100, 150 and 200 amp service, instead of the old 60 amp services that were common before 1960 or so.

The end result is that, today, you get to pick which way to go. The determining factor to most homebrewing hams now is "what parts do I have/can get?" You can go the "modern" way with silicon rectifiers and a capacitor bank (you need lots of MFD's, though), or the "old" way with either tube or silicon rectifiers, a suitable input choke, and a much smaller capacitor.

Complete design info is available in the ARRL Radio Amateur's Handbook. Trouble is, if you want the info on choke-input, you have to look at an older edition. It's all pretty simple, though.

Any more questions? I can describe the whole design process, but this post is long enough as it is.

I run a pair of 866As into a choke input filter for my homebrew rig. Great regulation, low power factor, smooooooooooooth DC. Sure it's big and heavy, but the parts cost me pennies at hamfests. And the MV flash is always nice to look at. 'Specially at 3 AM on Field Day.

Irrespective of the series impedance, the cases of zero and infinite
resistance are just the bounds of the mathematics and are, in the
present context, complete red herrings.

Lyle, a nice logical explanation !

Maximum power transfer theorems and conjugate matches were known well before the advent of radio, in the telegraph and telephone era. They are so obvious the early engineers didn't even bother to give them a name.

More recent generations, especially the amateur radio fraternity, like to give titles to their arguments - all belligerents feel the need for banners to fight under.

All excellent info! I would just add that normally to maintain regulation with a choke input filter, a certain minimum quiescent current through the choke is required. (While the current is below the critical value, the supply acts as a capacitor input filter) This usually requires a bleeder resistance value much lower than that required for safety. There are (were) "swinging chokes" that

varied their inductance in such a way as to minimize the required bleeder current. These chokes had a air gap which increase the inductance at lower current and let the choke saturate at higher currents.

Another way to lessen the bleeder current is to parallel resonate the choke at the ripple frequency.

To paraphrase Jim, you pays your money, you makes your choice. I have two supplies, one the factory supply for my Drake L4B. It has a fairly modern transformer, silicon rectifiers and a stack of electrolytic capacitors. DImensions are about 8" x 8" x 11".

My other supply has two surplus transformers, primaries in series on 240 VAC, secondaries independently bridge-rectified (so phasing isn't critical) and a tuned-choke input with an oil-filled capacitor. Size: 12 1/4" rack panel, 18" deep. Weight about 130 lbs. 3K @ 1A forever.

Which way to go with your new amp? I dunno. If I was thinking about doing a new one, I would seriously look at a high frequency switcher with electronic regulation. But that's a brand new topic.

If you put a speed limiter on a Corvette, it can only go as fast as the speed limiter. It seems, then, very strange to me to be talking about the _Corvette_ when the speed is maxed out by the _limiter_. If you want to talk about the Corvette, remove the artificial boundaries. YOU may not be discussing any other circuits, but there are others here that are discussing the Corvette with the speed limiter removed. It's simply a variation of the same circuit. If you don't want to know how much power you can really get from your model, connecting only to C2's plates, then keep your blinders on.

The comparison of maximizing power with a simple resistive load, then adding an inductor and seeing more power dissipated in the resistor isn't untrue, it's just extremely limited. With your model of C2 as an "antenna," I can very easily (given ideal inductors) get a whole lot MORE power dissipation in a load resistor than the way you suggested. Since the outer large plates are driven with a constant voltage, simply put a ONE ohm resistor in SERIES with an inductor which resonates the source impedance, maximizing resistor current. Now recalculate the load power, and see if it isn't bigger than with your high resistance value. Now drop the load resistance further, retune, and recalculate.

My gosh, it seems that we've discovered that we can "suck" infinite power from this puppy.

If you ever get back around to ANTENNAS instead of CAPACITORS, we'll get to re-introduce some resistance in the source impedance, and THAT will limit the available power.

That's not a direct answer to, "is the web site posting correct or not?" But I'll point out that John Larkin DID raise an issue with it in a posting a couple days ago, repeated below.
Cheers,
Tom

John Larkin wrote:

William,

I think your circuit model is too simplistic. In the no-inductor case, assume Rl is infinite; now reduce C1 (leave the C1 plates the same distance apart, but just reduce their area). Your simple circuit model predicts that the voltage across C1 approaches Vgen as the plates are made smaller, which is clearly not the case. The actual voltage across unloaded C1 is just

Vc1 = Vgen * d / D

where d = separation between C1 plates and D is separation between the big plates. Unloaded C1 degenerates to a pair of electrostatic field probes, irrespective of the plate area.

And why argue? Just build one and try it.

John

>the resistors.

My experience with making a dummy load into a 30dB attenuator was that the various parts should be shielded.

The T resistor network is particularly good for this, because you're working down at the 'cold' end of the big power resistor. I lifted the cold end and fed a short lead through a partition made from PC board. The shunt resistor to ground consisted of about 10 33-ohm 0.5W resistors arranged like spokes, and grounded with zero lead length on to the shield. Then a single 47-ohm resistor goes through the partition to the output socket, which is at the opposite end from the from the high-power input.

The attenuation was adjusted to exactly 30dB by a friend with a network analyser, who added/changed/subtracted shunt resistors to get it right. The resulting attenuation was very flat, up to at least 100MHz.

You couldn't get this performance with a Pi-attenuator, because of capacitance and inductance in the high-value series resistor (R2) which is also in a higher-impedance location. The T configuration has the advantage that all the shunt resistors are paralleled, so their self-inductances are divided by about 10, and the self-capacitance occurs in a low-impedance location where it doesn't seem to affect broadband performance.

30dB seems to be a kind of magic number, because you can use a standard 50-ohm power resistor without seriously affecting the input match. 20dB would require a special-value power resistor in order to give a good input match. 40dB would require an extremely low shunt resistor in the T

configuration, or a much higher series resistor in a Pi.

That arrangement works well for an air-cooled load, because it requires very little extra length inside an existing enclosure. It would obviously need more engineering to use oil cooling... you certainly wouldn't enjoy converting an existing oily Cantenna!

Yup. For 60 Hz power and full-wave rectification, the critical inductance works out to be L (in henries) >= Rload (kilohms). In other words, if your bleeder resistor is 20 kilohms, the input choke must be 20 Henries or larger to maintain critical inductance. Note that if your amp runs with any no-signal idling plate current, you can consider that current as part of the bleeder.

> There are (were) "swinging chokes" that
> varied their inductance in such a way as to minimize the required
bleeder
> current. These chokes had a air gap which increase the inductance at
lower
> current and let the choke saturate at higher currents.

All iron core power supply chokes have an airgap to prevent saturation. Smoothing chokes have a wide gap which makes the inductance fairly independent of the current - but you don't get as many henries that way. Swinging chokes use a narrow gap that gives more inductance at low current but less at high current. If you look at old catalogs, the choke manufacturers often made chokes that were essentially identical except that one was smoothing and the other was not. I have a pair of chokes that are the same size, weight, insulation and curent rating, but one is rated 20-4 Hy @ 30-300 mA (swinging choke) and the other is rated 8 Hy @ 0-300 mA (smoothing choke). This is typical of what you can expect.

In the old days it was common to use two filter sections - the first with a swinging choke and the second with a smoothing choke. This permitted the use of quite small filter caps - only a few mfd each. At the time, the cost of choke vs. cap was such that it made sense. Today, a single section is usually used, with more C.

You don't need perfect DC for a high power amp - 1% ripple is better than any mode requires.
>
> Another way to lessen the bleeder current is to parallel resonate the choke at
> the ripple frequency.

Yup, but you have to select the cap and choke to do it, because parts tolerances are pretty wide. The voltage across the choke/cap combo can get pretty high, too, and you want to use a smoothing, not swinging, choke. But it works!

There's one more point about these sort of supplies that bears mentioning. In the old days, manual T/R switching (PTT) was common, while VOX and QSK were not. It was common practice to use a separate plate transformer in the tx and turn off the HV when receiving, thus saving some power. This is practical with choke input, because of the low turn-on surge, but is rough with capacitor input. Most "modern" designs leave the HV on all the time, which wastes power on receive.

oh mama! Hope it's on wheels!

The stock L4B supply is undersized for full-power high-duty cycle operation of the amp, I am told. Fine for typical SSB, but if you like full-bore RTTY or SSTV, you need something bigger.

> Which way to go with your new amp? I dunno. If I was thinking about doing a new

Yep. And the design/construction of such a supply is much more complex than either of the conventional alternatives. I don't think you'd find the parts for a 3 kV 1 A switching supply at a hamfest...but then again, you never know!

> Let's see...

The Point is, that that value is NOT the same as the energy flux incident on the antenna. The power in the load is a result of how well you TRANSFER the POWER (also, don't equate voltage with power either) from the antenna to the load. Your circuit description ignores the fact that you arent capable of taking advantage of the full potential difference across the plates in the first case. Why? Because, for any frequency of oscillation, and any non-zero resistance, you will never be able to get all of the charge developed on the plates, which is also forms the current flowing through R, to flow through R before the the polarity of the voltage changes and hence, the sign of the charge induced on the plates changes. Insteaf of using the term resonance, just look at how much current flows.

Also, there is no advantage whatsoever to using the external capacitor and then going to the effort of calling your circuit a voltage divider leaving you with 2 capacitors in series with a resistor and capacitor in parallel. For any number of reasons such as it's always possible to separate the plates by an arbitrarily large distance so that the the capacitance -> 0 while keeping the voltage constant, so that the capacitance can be made arbitrarily small, and of no consequence while leaving the plates at any desired voltage with whatever time dependendence you want. I think I know where you are trying to go with this and are going to claim this feature is crucial, but it isn't and it only obfuscates the the physics. So, you can treat the circuit as having a voltage source attached to each plate, since that's what will appear from the charges induced by the E-field.

Then, the current flow into any junction = the flow out, so the current from the capacitor = the current through the resistor. The charge on the capacitor is q=cv, which gives you a current of i = c(dv/dt) and if the i through the resistor is v/r, v/r + c(dv/dt) = 0 -> dv/v = -rc dt and v(t) = v0 exp(-t/rc). The current is just i(t) = v(t)/r. If you are at 0 volts between the plates and you apply v0 across them, it will take infinitely long for the energy stored in the field of the capacitor due

to v0 to drive the charge to the other plate and therefore through the
If you try to apply the same voltage, but swap polarities, you need to
remove the leftover charges in addition to supplying enough new charge
to establish the ful potential difference. So, the current that would
have been dissapated in the resistor if it were left there does not
and cannot contribute to the power the resistor dissapates. After a
time t = RC, the voltage is down by 1/e and if 1/f is about equal to
that, you should be able to understand where the power goes. If, you
now consider the case V = Vo sin(wt) from q(t) = C v(t) you get
q(t) = C Vo cos(wt) and i = -Vo(wC) sin(wt). Through the resistor, the
voltage difference must be the same and the current is i = Vo cos(t).
Therefore, since the total current flowing into (or out from) a junction
must sum to zero, you get (at any point):

i(t) = wC *Vo sin(wt) + (Vo/R) cos(wt) = 0

Since sin(wt) is Im exp(jwt) and cos(wt) is the Re part,
and j = exp(j*pi/2), I can rewrite this as:

i = Re(jwC + 1/R)Vo exp(jwt)

You can see that it is never possible to make all of the current flow
through the load resistor. The current is divided between the two
in proportion to the phase angle between them. That has to be 0
for the resistor to receive all of the current and hence, dissipate
the energy.

What happens in your second picture where there is now an inductor
in parallel? Well, the Voltage is still the same, but is divided between
all three. Since the current through the inductor is given through the
relation, V = Vo cos(wt) (-L)(di/dt), you get:

i = (Vo/wL) sin(wt)

This is the Re part of (-Vo/jwL) exp(jwt). So all three give you:

i = Re [(jwC - 1/wL) + (1/R)]Vo exp(jwt)

You can apparently make all of the current appear in the resistor
by a careful choice for L,C and w. Why does this happen? Because
the energy that the resistor would normally not have available,
is stored by the inductor. Since neither an inductor or capacitor
dissipates energy, that "missing energy" in the first case is
no longer "missing"

> indeed gives the maximum Pd. If this is wrong, please
> tell me where the error is. It would also help if
> you could say what the value for R1 should be, rather
> than the 3.2K I calculate.
>
But the reason it's a maximum is NOT because that's all that
was there. It's maximized because there is no way to make
that phase angle 0 if C is mot zero and no inductor is present.

The imaginary part of the impedance corresonds to stored and
UNAVAILABLE energy that is added and removed by the souce
as the voltage cycles. That requirement that 1/wc = R is
because if 1/wc is very large, the impedance is low and
R doesn't recive a large fraction of the current so P=IV
is small, If R is very small, then the power the resistor can
dissipate is small (recall a perfect short dissipates no
power at all). The number you have calculated is just the
maximum of the the expression for the power dissipated,
not the total energy of the system.

> my intent with R1 is to find the best resistance value,
> not the matched impedance value, and then to compare it
> with an identical "antenna" which has an added inductor
> to create resonance. I'll go fix my incorrect "impedance
> matching" wording on the webpage.
>
But, they aren't identical antennas in that case! The
matching is crucial to TRANSFER the energy to your
resistor rather than re-radiate it. That's what an
impedance mismatch and reflection are - the energy
that's available but cant be removed from the system.
Energy is conserved by re-radiating that which you

Sure. The function has a minimum. But that corresponds
only to the Re part. You aren't working with all of the
current when you do that.

> So you agree that the calculated power ratio of 100:1
> between the two antennas on the webpage is correct?

It doesn't matter. If you made a mistake, correcting
it only will give you the same type of disparity
at a 10:1 or 1000:1 or whatever. The point is, that's
nothing but an impedance issue that prevents you from
removing the energy available to the system through
that resistor. It isn't the total energy there.

> Do you also agree that the e-field near the C2 plates
> is far stronger than the e-field near the plates of C1?
> Or am I mistaken about this strong e-field?
>
The relationship between the E fields is and always has been
in such a configuration, dependent upon the sum of the separate
fields. If the plates are connected so that the top of the

inner is connected to the top outer and the same for
the two bottom plates, the E-field will be higher between
the plates on the inner capacitor. If on the other hand,
the two inner plates are shorted, the field between the plates
of the inner cap will always be 0. If they are left to float
the fields will bee the same between the inner plates as
anywhere else within the larger cap. If you tie the plates
together with resistors, capacitors and inductors, then
the result is still determined explicitly, but now you
are storing the energy in other components. As to which is
stronger in your specific question, why does it matter?
You can make them turn out however you like by choosing the
components.

> The stuff on that website is DEAD SIMPLE. If the 100:1
> difference in energy is wrong, and if the large voltage
> and e-field associated with the C2 plates is wrong, then
> somebody who knows simple AC circuitry should be able to
> point out the glaring errors.
>

And it doesnt relate to an antenna. You got ahead of yourself.
You have to interperet this first. You've already skipped to
measuring fields before deciding what they should be. If you
now calculate the fields, you wont find any difference in
that and what a measurement should yield and will. You are
exchanging cause and effect. The field around the antenna is
a superposition of the incoming and re-radiated fields, just
like holding a mirror up redirects the light. For the same
reason, even.

An R value of 3.2k gives the maximum Pd in your simple series R-C
circuit. But nobody who wants to maximize power transfer would use a
simple R-C circuit. They would use a conjugate matching network instead.

But what is the significance of this initial circuit, other than to show
that if you use the wrong matching network, you can easily improve upon
it?

I should have stated that load resistor would be placed in series with
the inductor, not in parallel with it. The complex (that is, involving
real and imaginary numbers) expression for a series circuit impedance is
immediately obvious; for a parallel circuit it is not. That's why I
think in terms of series circuits whenever possible. Because your source
impedance is zero, it should be possible to extract _any_ desired power
from the source by allowing the load resistance to go toward zero (with
the resistor in series with the inductor) or toward infinity (with the
resistor in parallel as shown in your circuit).

The power calculation is probably correct for the condition where the L and C in parallel with the resistor form a parallel resonant circuit, because as you point out, the parallel L-C network has an infinite impedance, leaving only your 320k resistor and Ca, the 1 pF capacitor. But that is not the condition for maximum power transfer!! You are only getting 16 milliwatts out of your circuit, compared to a theoretical maximum of infinity. For maximum power transfer, you need resonance in the _entire_ network, including capacitor Ca. This is fairly easy to do. Simply increase the value of L1 a tiny bit beyond what it takes to resonate with C2. This makes the L1-C2 combination look like a very large inductor, and by choosing the correct value, it now resonates with Ca to form a voltage-multiplying circuit. Black magic -- it's now possible to get more than 100 volts across R! In fact, with your 320k resistor in the circuit and a slight amount of retuning, you can extract considerably more than your calculated 16 milliwatts. Increase R to 100 megohms, and you can get about 20 watts. (Unfortunately you need components with a Q of over 30,000 to do this.) The math needed to arrive at the numbers I've quoted is conventional but tedious; I cheated and used a circuit analysis program (MicroSim) to solve the equations.

> So you agree that the calculated power ratio of 100:1
> between the two antennas on the webpage is correct?

Yes, it's true for your example, but as Tom Bruhns has pointed out, your "matching" circuit is like putting a speed limiter on a Corvette. It's possible to do much better than the numbers in your example if the circuit is truly matched.

>
> Do you also agree that the e-field near the C2 plates
> is far stronger than the e-field near the plates of C1?
> Or am I mistaken about this strong e-field?
>

Yes, there can be a very strong e-field in the vicinity of C1 if circuit Q is high and things are tuned correctly.

Source record: 62432

I'm happy to report that Chip (the ol' man himself) will be on this weekend on 10M with the Fractal Quad Yagi, working Europeans. He will be on about 1300 UTC somewhere in or near about 28490 to 28500 KHz. He will try (but no promises) to get on both days of the weekend so take a listen to see how that lil' fractal antenna plays! Usually he stays on an hour or so.

Background info can be found on the ham page on

http://www.fractenna.com

Chip's fractal antenna work has appeared in RadCom, Practical Wireless, World Radio News, 73, Communications Quarterly, Radio Revisita, Monitoring Times, QTC, Scientific American, Discover, Science et Vie, and many other magazines.

Hear and work the latest innovation to the world of antennas from Chip himself:-)

not sure where you got it from that capacitor input means "no choke"
This is rather simplified, and just not true

but as you say "id depends"
yes, it depends whether you have a pi-type filter or just a capacitor

If we do not deal with swinging chokes, I vote for the capacitor input
filter since it has higher efficiency than only capacitor filter, see
explanation above

That's an interesting idea. With the dummy load I was planning to use,
there isn't really much room to "float" the ground end of the power
resistor - mechanical tolerances are pretty tight. There is room
to "tap" the hot end easily, which is why I was thinking about a pi
network. But I do have a different load where it would be easier to
get access to the ground end of the resistor.

>You couldn't get this performance with a Pi-attenuator, because of
>capacitance and inductance in the high-value series resistor (R2) which

I was planning to use surface-mount resistors, to minimize capacitance
and inductance - probably 2 10k in series, in series with 2 more 10k
in parallel for a total of 25k.

>30dB seems to be a kind of magic number, because you can use a standard

40 dB needs a 1 ohm resistor for the shunt. That should be doable
with 10 10R surface-mount resistors. With 50 W in, they need to
dissipate 1/10 W each, which seems plausible.

Looks good from a distance. Haven't got close enough to confirm beyond
doubt though.

> my intent with R1 is to find the best resistance value,

Best meaning that which causes maximum power dissipation.

> not the matched impedance value, and then to compare it
> with an identical "antenna" which has an added inductor
> to create resonance. I'll go fix my incorrect "impedance
> matching" wording on the webpage.

Yeah, but if you add an inductor, the previously computed R1 isn't going to be best any more since you've upset the above formula.

> > It just happens that this is the condition
> > for resonance. Since the real part of the "source" impedance is zero,
> > maximum power transfer also requires that the load resistor be made
> > equal to zero.
>
> Oops! Ooops! max power at ZERO ohms?

Yes perfectly reasonable. If your source impedance is exactly zero ohms resistive, then the max power theorem says that you have to have a 0 ohm load to get max power transfer. Of course this doesn't happen, it's just one end point of the graph of the power transfer equation. Note that it's also the infinite power end since any voltage at all on a zero ohm load gives infinite current and hence infinite power. The other end of the graph says if you have infinite source resistance, you need infinite load resistance to get maximum power. But since that "maximum" power transferred would be zero watts, it really doesn't matter what the load resistance is...

> > Unfortunately, it takes infinite current to produce any
> > power dissipation in a zero ohm resistor, but that's a
> > minor detail.
>
> This is wrong.

No it's not! In fact, it's equivalent to the statement that it takes infinite current to get any voltage drop across a 0 ohm resistor. That statement above is referring to any load in general, not in your circuit. Power in a resistor is current squared times resistance. If R is zero, the ONLY way power is going to be non-zero is if current squared is infinite. And that means infinite current.

Fortunately, it only takes a very small (nearly, but not quite infinitely small) voltage across a 0 ohm resistor to produce this infininte current. Since current is V on R. If R is zero, and V is ANYTHING OTHER THAN zero, then the current must be infinite! So now all we need to do is define a 1microvolt infinite current power supply, and we can dissipate (lots, hell infinite) power in the zero ohm load!!

We're not arguing EM physics now, we're losing sight of ohms law. Better be REAL careful now...

> Power goes DOWN if I reduce R2

In your circuit yes. That's because the Current goes down if you reduce R2.

> below 320K. If I reduce the value of R2, then the

There's the difference. Your circuit is current limited, the other guy's
isn't.

Sounds good... As long as it's still not more power than the impinging EM
wave that's hitting the antenna there's nothing wrong with this either.
It just means your putting more of the available power into he load instead
of (re)radiating it into space.

> Do you also agree that the e-field near the C2 plates

Pass. As I say, from a distance it sort of looks OK.

David.

Try Murph's Surplus in CA. They have a web page and I think I saw
some nixie tubes there last week.

I think I see now.

Instead of being limited to 100V, the voltage across the
(lossless) inductor will rise towards infinity, right?
Put a large resistance across the parallel LC circuit
(or a much smaller resistance in series), and you can
extract as much energy as you want. In theory.

> The resonant network is an inverse impedance transformer, so

That's what I thought. The increased power in the load attached to the resonant antenna is a familiar principle. (This says nothing about practical considerations for extracting huge energy flows, of course.)

The next question: What happens if we remove the large metal driver-plates shown in that article, and instead place this electrically small, lossless resonant antenna a few tens of KM away from a 500KHz CW radio station? Orient the capacitor/dipole for best reception, of course.

Doesn't a similar effect arise with EM waves? Or does it only work with the capacitive coupling I've shown? Does the effect vanish if the e-field is part of a propagating EM wave?

I'm under the impression that the small resonant antenna can intercept energy from throughout its surrounding nearfield region (a spherical volume of approximately 1/pi wavelengths in diameter.) At 500KHz, the small antenna, if it was built from lossless components, could behave as if it was about 200 meters across. No? And it would "become" even larger at VLF?

Obviously. There is no fantasy involved. The stuff
on http://www.amasci.com/tesla/nearfld1.html is basic
physics, and it is clearly labled as a simplified model.
The components are assumed to be lossless. I'm asking
whether R2 gets more power than R1 IN PRINCIPLE. In
practice, with the inductor's resistance lowering the
Q of the resonator, things may be very different. But
first things first. I want to explore the predictions
made by conventional circuit theory about these circuit
elements, if lossless components are used.

> If you cannot understand

> on fundamentals
> before proceeding to revolutionize the economy of the
> world with breakthrough physics.

OK, you say that there is a flaw in that webpage article,
in the part involving R1 and C1.

Does this flaw alter my conclusion that the power in R2
is much higher than the power in R1? If the problem you
found is fixed, how does it impact the equations?

And most important, does it alter my conclusion that the
presence of a resonator can increase the power available
to a load resistor?

> But I'll offer a hint: Slit each of the capacitor plates in half and
> analyze what happens. You may slit them on any axis.

I'm not willing to play this gussing game. If you've
discovered that the power in R2 should not be greater than

the power in R1, please demonstrate this. If you cannot,
then I shall assume that my conclusion about the increased
power in R2 have not yet been proven incorrect.

I believe that the real problem involves my explanation. My
explanation might very well be incorrect, yet the phenomenon
in question still is real. Unfortunately, the folks on
sci.physics.electromag, in order to "stop me" or something,
are distorting physics itself, and trying to say that
the conclusions on http://www.amasci.com/tesla/nearfld1.html
go against physical law. I am moved to ask: who presents
the greater "danger" to physics, those like me who excitedly
discover interesting aspects and then explain it WRONG, or
those who conveniently alter it as needed, whenever they
wish to "defend" it against threats?

I am here to root out my errors. I suspect that the same is
not true of everyone here.

If my conclusions depicted on
http://www.amasci.com/tesla/nearfld1.html
are correct, obviously this DOES NOT MEAN that my explanation
on other parts of my website is correct. I cannot use
the nearfld1.html article to "prove" my explanation, I can
only use it to demonstrate the reality of the phenomenon I'm
trying hard to explain to myself.

Can an electrically small antenna intercept much more
energy when it has a resonator, than if it does not? Simple
question. And contrary to those who loudly insist that
the answer is not interesting, I think that it is.

> I assume that I'm the 'asshole' you refer to. Well, I'm always willing

> general and Maxwell's equations in particular, without having done any
> of the basic homework, and challenges us to help him, I am somehow
> less sympathetic. Reminds me of the 'Flavored Coffee Guy', a sad case
> indeed.

There are two separate issues here:

1. Does the phenomenon exist? Do electrically small
dipole or loop antennas, if they are part of a high-Q
resonator, allow interception of more power than if the
resonator is not present?

2. Is Bill Beaty's explanation of this effect a load
of crap?

The answer to #1 is not totally clear as yet. When applied
to the e-field between a pair of metal plates, it appears
that a resonant antenna DOES work far better than one
without a resonator. (There was an error on my webpage,
but it involved L1 and C2, and it caused me to vastly
UNDER-estimate the theoretical limits on power. My
100:1 ratio was wrong. It is much, much higher.)

The next stage is to remove the metal plates and replace
them with the e-field which is part of some propagating EM
waves coming from a distant transmitter. If this is done,
does R1, the resistor attached to the resonant antenna,
still get more power than R2? I believe the answer is
yes. Is the limit on the R2 power still at infinity?
Obviously not. Instead, I understand that the tiny
resonant antenna can only intercept EM energy in a
spherical region around itself, where the diameter of the
sphere is the nearfield region of that antenna, or roughly
1/pi wavelengths. (Notice that I'm not trying to explain
why this is so at this point. I only state that it occurs.
Well, if lossless components are used, it would occur.)

So what imnpedance does the antenna present before and after you throw the load across it.

I strongly suspect that you will find that this is pretty damn important, and explains your problem understanding how much energy the antenna is able to deliver.

I see no inclusion in your analysis of the impedance of your antenna and load.

The effect of this is non trivial, and has a fundamental effect on bopth the antenna, its effective size and I suspect your "problem" with understanding what is going on in your postulated problem.

I suggest that you get a decent book on antennas and have a read, antenna behaviour analysis does not respond well to simplification unless it is very carefully thought out.

Someone pointed out some months back that you need to double the
incoming signal and lock to that if you are trying to demodulate
DSB with no carrier (or I suppose AM where the carrier has been lost
along the way). I'd seen circuits that that, but until that post
I hadn't quite figured out the point. Could that be the reason
for a 910KHz VCO? If you have to divide the VCO by two to get
a 455KHz signal, surely there is as much chance for the signal
to bet back into the IF strip than if you started with a 455KHz VCO.

There was an article in Ham Radio back in the 70s by Henry S. Keen
that had something along this lines, but I can't remember the details
and it would take too long to find it. Either he came up with a phase
detector that locked on the harmonic, come to think of it, all analog
phase detectors will do that, or he had some scheme where the VCO
at twice the IF provided the carrier without division. I
guess I should try to find that article.

And the Drake R-8 receiver has a synchronous detector where the VCO
runs at twice the IF. The circuit is in Communications Quarterly for
Fall 1992. It looks like a complicated circuit, because there's switching
so the circuit works on CW/SSB, but it uses an MC1496 as the balanced
modulator. The incoming signal is also doubled, and it feeds a 4046 PLL

running at twice the IF. A CMOS divider brings the VCO signal down
to the IF frequency, where it feeds the 1496.

You're right that there isn't often a lot of use for fancy AM detectors,
but nevertheless it is interesting. For most of the time radio has
been around, a simple diode detector has been the demodulator for AM.
Yes, synchronous detectors were around for a long time, CQ had one
complete with a phasing network for selectable sideband back in the fifties,
and QST had an article in 1964, but in the days of tubes they were too
bulky to be useful. Then, as AM was fading out for communication work,
semiconductors came along and allowed fancier techniques. But it's only
been the past ten to fifteen years that "sychronous detectors" have
been commonly known, mainly because a lot of shortwave receivers
have them now.

Even beyond synchronous and quasi-synchronous detectors, there are
possibilities for better AM detectors. Bias a diode so it can better
deal with small voltage levels. Or put the diode in the loop of an
op-amp, That's not a new idea, but nowadays there are op-amps that
can better deal with IF frequencies than in the days of the 741.

So while there may not be a lot of reason for a better AM detector,
the process of exploring alternatives to the simple diode detectors
may have value that can't be defined.

Obviously. Notice that I'm not asserting anything about
energy flux at this point. I'm only trying to cut through
the complexity and get a straight answer: does the power
in R2 exceed the power in R1? Is the e-field near the
C2 plates stronger than the e-field at the same position
near C1? If some people in this thread say "NO!", then I'd
like to hear their arguments.

Do you accept that the power in R2 is higher, in the situation
depicted on http://www.amasci.com/tesla/nearfld1.html ?

If you give me a clear answer to this simple question,
then we can go on to other issues. Or if you're sick of the
whole thing, I can continue the discussion with others
who can still stomache it. :)

> endence you want.

I'm not doing any of the things above, or discussing such
things. I'm only discussing the circuits on that webpage,
and whether R2 has higher power than R1. My intent is to

place a simplified model of an antenna in an e-field
which is generated by a power supply, then to add a
resonator and see what difference it makes.

Any changes made to my capacitor-plates setup can only
serve to sow doubt and confusion. I choose to pursue
simplicity instead, and therefore to keep my capacitor-
plates setup just as it is.

> I think I know where you are trying to go with this
> and are going to claim this feature is crucial, but it isn't and it

Notice that I'm not claiming anything yet. I'm only
asking some simple questions.

> The imaginary part of the impedance corresonds to stored and

> dissipate is small (recall a perfect short dissipates no
> power at all). The number you have calculated is just the
> maximum of the the expression for the power dissipated,
> not the total energy of the system.

I'm not yet discussing the details of this system. I'm
only looking for some agreement on whether the power in
R2 is significantly higher than the power in R1.

> > my intent with R1 is to find the best resistance value,

> >
> But, they aren't identical antennas in that case!

By "antenna" in the above, I mean the metal
plates C1 or C2. These later can serve as a simplified
model of an electrically short dipole antenna, and C1 and
C2 must be identical, in order that I can see what effect
the presence of L1 has, when tuned to resonance.

But first I want to know, does R2 run hotter than R1,
and is the e-field near C2 stronger than the e-field
near C1?

> > So you agree that the calculated power ratio of 100:1

> it only will give you the same type of disparity
> at a 10:1 or 1000:1 or whatever.

I agree. I only want to know if the L1-C2-R2 device
has more power in its load resistor than the C1-R1 device.
I'm not yet discussing why, or yet trying to explain it,
or pursuing implications. I only want to get some agreement
that it actually occurs in the setup that I've shown.

> > Do you also agree that the e-field near the C2 plates

> the plates on the inner capacitor.

I'm not discussing anything except the two devices
illustrated on http://www.amasci.com/tesla/nearfld1.html,
with no changes made, and with the operating conditions
kept just as I've stated.

Is the strength of the e-field adjacent to the C2
plates far stronger than the e-field in the same
location near the C1 plates?

If on the other hand,
> the two inner plates are shorted, the field between the plates

> components.

I can make the results of this thought-experiment be
anything I like? That's a good tactic, if my goal was
to "win the fight" rather than to examine some physics.

You are right: I could easily use my expertise in physics
to create illusory complexity in order to sow confusion
and deflect enquiry. It's very useful skill in sci-
newsgroup flamewars where the enemy must be defeated at
any cost. However, it's very damaging when used in a
scientific discussion, where clarity and understanding
are the goals.

If instead the goal is to illuminate concepts, then
extreme simplicity works well. Simplicity allows ideas
to gain their own voices, and they need far less
interpretation.

>
> And it doesnt relate to an antenna. You got ahead of yourself.
> You have to interperet this first.

Until I hear clear answers to my simple questions, I'm not
relating it to anything. I'm not discussing "energy
sucking antennas" anymore, or any implications of these
circuits, or what occurs in variants of them. I'm
only discussing what happens in the situation as
depicted on http://www.amasci.com/tesla/nearfld1.html

> You've already skipped to
> measuring fields before deciding what they should be. If you
> now calculate the fields, you wont find any difference in
> that and what a measurement should yield and will. You are
> exchanging cause and effect.

I'm doing none of this. I'm asking this question: is the
strength of the e-field adjacent to the C2 plates
much stronger than the e-field adjacent to the C1 plates?
With the circuits and plates kept exactly as they are?
Yes or no. I don't care what the actual values are, I
only want to know if one of them is much stronger than
the other. Without a clear answer I can see no way
to go forward with any discussion.

Ecah time I've scrounged up a cellphone, I've taken it apart as soon
as I got home. It was sort of like unwrapping a Christmas present;
I was wanting to know what was inside. And so I stupidly didn't
keep track of the make and models of the phones. I should have,
because as I said, the oldest of the three had more discrete and
old fashioned parts than the newer ones that had a lof of surface
mount.

The first one I took apart, with a first IF in the 80MHz range, had
a nice little module that clearly was the IF strip. I got it off
the circuit board, and there were only a handful of pins that should
be easy to figure out when I get around to it. IF in, audio out,
power, ground, maybe a squelch level. The filters were what gave
the module away.

The other two were less neat, with the componenets soldered onto
a larger board.

I would think they used common ICs for the IF strip, though I don't
have them in front of me. Even if the IC had an odd number, I would
make a guess that they are common ICs. I'd use the old trick of
checking familiar IC pinouts to what was there, and if there was
even a little match, I'd check further.

If there wasn't a match, and there wasn't a well defined stand
alone module, I probably wouldn't bother extracting the whole IF
strip. Take out the filters, making sure to sketch out the connections

and the terminating resistors, and the crystal for beating down to the final IF. Those are the valuable parts, with the IC like icing if you can identify it.

I thought you might like to know. "Morph" words crop up
frequently in technical talk and it's easy to be misled. I
have always thought that "anthropic" could use another
syllable anyway.

If you have infinite Q, then in infinite time you'd have
infinite voltage (assuming your source is a perfect
current source, which it never will be). But of course
you don't have infinite Q, even if the capacitor and
inductor are lossless, because R isn't infinite. The
loaded Q of the circuit limits the voltage rise to
a finite value.

You don't have infinite time either, you have 1/(2f).
After 1/(2f) reradiation begins, and energy is lost by
the antenna.

Note, if you have a constant voltage source instead of a
constant current source, then that obviously limits the
voltage rise to less than infinity. But if it is a perfect
constant voltage source (it won't be) then current can
rise toward infinity as R tends toward zero.

But all real sources are power limited, so there are no
infinities. With a constant current source, at some point
the current starts to decline because you've run into the
voltage limits of the supply. With a constant voltage
source, voltage begins to sag as you run into the current
limits of the supply.

For a power limited source, maximum output occurs
when the load impedance is the conjugate match of the
source dynamic impedance.

> That's what I thought. The increased power in the
> load attached to the resonant antenna is a familiar
> principle. (This says nothing about practical
> considerations for extracting huge energy flows, of
> course.)

Well, the *antenna* isn't resonant. It is electrically
short, remember? So it is very reactive. All we've
done is to present it with a load whose impedance
is the complex conjugate of the source. The antenna
is unchanged. It is still the short highly reactive antenna
it has always been. The load is different.

In other words, the antenna is still Ra-jXa, but now the
load is Rb+jXb. We've arranged values so that Ra=Rb,
and Xa + Xb = 0. This is the conjugate match condition.

> The next question: What happens if we remove the large
> metal driver-plates shown in that article, and instead
> place this electrically small, lossless resonant antenna
> a few tens of KM away from a 500KHz CW radio station?
> Orient the capacitor/dipole for best reception, of
> course.

Well the small stray coupling capacitors of your model
go away. So your voltage divider analysis is no longer
valid.

> Doesn't a similar effect arise with EM waves? Or does
> it only work with the capacitive coupling I've shown?
> Does the effect vanish if the e-field is part of a
> propagating EM wave?

If by "effect" you mean conjugate matching, no it does not go
away. However, the source impedance changes dramatically.
So the values of L and R must change in order to restore the
conjugate match. Due to inverse square spreading, the "source"
is also effectively power limited at the receive site to a *much*
smaller value than the power at the transmitter.

> I'm under the impression that the small resonant antenna
> can intercept energy from throughout its surrounding

> antenna, if it was built from lossless components, could
> behave as if it was about 200 meters across. No?
> And it would "become" even larger at VLF?

That's a backwards way of looking at it. A truer analogy
is to say that the photons are "larger" at lower frequencies.
Since the photon represents the smallest unit of EM energy
at that frequency, your antenna will absorb all or none of its
energy if it encounters any "part" of the photon.

Lets think of it this way. Suppose you have a razor blade mounted edge on to a cannon firing water balloons. If the razor blade encounters any part of the balloon, it bursts releasing all of its water. Say this is a halfwave antenna. Now replace the razor blade with a very sharp needle point. This is your very small antenna. The balloon still bursts if any part of it encounters the needle.

We can look at the antenna situation similarly, with the added quantum mechanical quirk that the antenna gets all the energy from the photon when it "bursts".

If the balloons are made larger, the cannon doesn't have to be pointed as accurately to encounter the needle. Similarly, as frequency is decreased, and consequently the photon wavelength becomes larger, the very small antenna encounters parts of photons which are pointed further off axis. In other words, the target isn't getting larger, the bullets are. If we look at this classically, we say the antenna aperture is larger, but what's really larger are the bullets (photons) being fired at it.

Note that photons don't have a size in a classical sense. What is meant by this analogy is that the probability wave function covers a larger area at lower frequencies. It collapses to the antenna location when "pricked" by the antenna, and the photon gives up its energy by accelerating a charge on the antenna.

2148. Raytheon JAN 6088 circuits wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-18 00:00:00 UTC

Message-ID: <OVGA4.3905$F3.185732608@news.telia.no>
Source record: 62307

Hi gang!

I am looking for info on how to build my own shortwave receiver using Raytheon JAN 6088 tubes. These tubes are of the "battery" or "pencil" type and are small, low current/voltage devices. On the net I have found only one place of real info on this tube, at http://members.aol.com/sbench101/BatteryPoweredAmps/submin.html , and this is fine as long as it goes, but I really would like to find (radio or whatever) schematics and applications for this cute looking tube. Actually, ANY info on these small devices will be much appreciated!

I do not have too much experience in building radios, but I have done some transistor/IC builds from designs in various electronics magazines. I do have circuit diagrams for sw radios using "ordinary" tubes, but these seems to be of not much help.. I'm very aware that I have limited knowledge with tubes! :-)

My goal would be to build a superheterodyne radio for the shortwave broadcast bands. But I will start slovly, make a TRF first.

Willy

> Any changes made to my capacitor-plates setup can only
> serve to sow doubt and confusion. I choose to pursue

Excuse me for thinking RLC was simpler than C in series with RLC in
serires wuth C. What WAS I thinking?

> simplicity instead, and therefore to keep my capacitor-
> plates setup just as it is.
>
Yes, of course as I just mentioned, this escaped me. I kept
thing the additional parts that serve no purpose actually
serve no purpose.

> Notice that I'm not claiming anything yet. I'm only
> asking some simple questions.
>
Just simple enough to include the obfuscation. To quote einstein
"make it as simple as possible, but no simpler". Since all of
the physics is in the inner stuff, it doesn't seem like you can
remove the outer plates without eliminating the obfuscatory
capability of the design.

> By "antenna" in the above, I mean the metal
> plates C1 or C2. These later can serve as a simplified
> model of an electrically short dipole antenna, and C1 and

No. By antenna I meant ox cart. sheesh. One capacitor serves that
purpose. Two does not unless your purpose is to describe two dipoles
with different dipole moments that are capacitively coupled and then
pretend it isnt.

> or pursuing implications. I only want to get some agreement
> that it actually occurs in the setup that I've shown.
>
I made it simpler. I let you use any ratio you want. I dont fucking care.
Use P1 and P2 for christ's sake. jeeez. If that doesnt do it for you
and this ratio of 100:1 is drop-forged into your skill, I cant help --
I'm not a brain surgeon. I know when it's time to cut my losses on
a pointless time sink that's already taken more time from pounding my head
into the sidewalk than it deserves.

>
> I'm not discussing anything except the two devices

> kept just as I've stated.
>

Enjoy it. You have N-1 people willing to be fooled by claims that this
is a discussion. And the text from "except" onward is unnecessary and
detracts from "anthing".

> I can make the results of this thought-experiment be
> anything I like?

That's why people refer to them as "thought experiments". If you'd
like limitations, go buy some parts and build a real one.

> That's a good tactic, if my goal was
> to "win the fight" rather than to examine some physics.
>
Then, _I'm_ mystified. There is as of yet, no physics to examine.

> You are right: I could easily use my expertise in physics

No, apparently not. Expertise would have stripped the superfluos
crap from the components in the figures by applying such expertise.
Instead, you've applied your knowledge of magic to direct attention
to useless inclusions.

> to create illusory complexity in order to sow confusion
> and deflect enquiry. It's very useful skill in sci-

How does that differ from creating illusory complexity in order
to sow confusion and deflect enquiry"?.

> newsgroup flamewars where the enemy must be defeated at
> any cost. However, it's very damaging when used in a

That may be, but find another person willing to pay you for annealing.
I'm willing to be defeated as soon as the law of diminishing returns
indicates I'd be better off trying to convinve the pope to elevate
the sisters of perpetual indulgence to sainthood or to convince the amish
to buy microwave ovens.

> scientific discussion, where clarity and understanding
> are the goals.
>
I guess I missed that thread.

> If instead the goal is to illuminate concepts, then

Then, you'll need a bulb and some batteries. Wishing has yet to
be a reliable substitute for either.

> extreme simplicity works well. Simplicity allows ideas

How can you tell? You keep avoiding it.

> to gain their own voices, and they need far less
> interpretation.
>

I take it then, you have a different objective that requires
the additional, unnecessary pieces than you can obtain with
a simple picture.

> Until I hear clear answers to my simple questions, I'm not
> relating it to anything. I'm not discussing "energy
> sucking antennas" anymore, or any implications of these

Have a nice day.

> circuits, or what occurs in variants of them. I'm
> only discussing what happens in the situation as
> depicted on http://www.amasci.com/tesla/nearfld1.html

With whom? Your fans? Time wasting isn't all that popular.

> With the circuits and plates kept exactly as they are?
> Yes or no. I don't care what the actual values are, I

Yes, you do., since I answered all of this along with descriptions
of the charges flowing and stored energy in great detail for the
general case, so that "why" would be obvious to a casual observer.
I now just need to qualify, "obvious" and "casual observer" to be
more restricted sets.

> only want to know if one of them is much stronger than
> the other.

No you don't or you wouldnt be repeating this request as a response
to something containing the answer.

> Without a clear answer I can see no way
> to go forward with any discussion.
>

You wont be able to see a way to go forward unless you can get
a checkbox response to the entire process that led you to your
misunderstanding of the physics involved. I'm afraid I dont
see what I get out of following you to unenlightenment.

If you want it your way, I recommend burger king rather than posting
to usenet where no one gets paid to pander to nonsense or fired for
noticing bullshit.

Who said anything about photons? If i put a magnet near a ball-bearing,
and cause the ball-bearing to start rolling along a flat surface, i have
transferred energy to it. Any photons?

This is an age-old problem. Yes, there are people who wish to 'preserve
order' by suppressing 'inconvenient' facts. These days, in electrical
science, they usually get short shrift if they are found out, but some
can disguise their stance and get away with it for some time. I recall
about 20 years ago a recurrence of the 'flux linking/flux cutting'
argument and a proposal to stop telling students about, for example,
Faraday's Disc, and other constructions that highlight the subject. It
was not favourably received! I hope that these days there is no longer a
problem in this area because students are taught a form of Faraday's Law
which does not produce the false controversy.

That's what I'm saying.

You need filtering, but not to the same level required in a receiver or low-level transmitter stages. You need the voltage to be reasonably constant (say, 5%) but not electronically regulated.

>not sure where you got it from that capacitor input means "no choke"
>This is rather simplified, and just not true

I didn't say it meant "no choke" in all designs.

The question was about power supplies for high-power RF amplifiers. On this side of the pond, capacitor-only filters have been used since the 1960s for such purposes.
>
>but as you say "id depends"
>yes, it depends whether you have a pi-type filter or just a capacitor

Very few high power amateur transmitters that I've seen use a pi-type filter.
>
>If we do not deal with swinging chokes, I vote for the capacitor input
>filter since it has higher efficiency than only capacitor filter, see
>explanation above

All factors have to be considered. Efficiency is important - but so is cost, size, ripple, voltage variation from full-to-no-load, and component availability. The "best" design is useless if you can't get the parts.

totally reversed/misunderstood
The problem is that the oscillator, and tuned circuits radiates,
possibly due to some magnetic coupling, while a divider with short
connection to another IC cannot radiate

Jim W8ZR:

I went through this same thing a few
months back. Bought an older style
18 Ghz. Systron Donner frequency meter
on e-Bay for $60, and one of the display's
Nixie tubes was cracked on receipt.

Found a few places listed on the InterNet
that said they had them, but when I went to
order them, they didn't have any in stock.

Locally Richardson Electronics has them
new for only $90.00 each; and another
place, in New York I think, had them for
only, $110.00 each! The N.Y. guy got
mad when I politely explained that I only
paid $60 total for this unit, which still has
8 good Nixie tubes in it. For a while their
I was thinking of selling the other good 8
Nixie tubes at $100 each, and making a
$800 + profit, NOT!

Anyway, I did eventually find two places
that have Nixie Display tubes at reasonable
(~$20) prices, and did buy 3 from the latter.

1) Antique Electronic Supply, Tempe, Az.
(480) 820-5411
2) Sphere Research Corporation BC, Canada
http://www.sphere.bc.ca/test/nixies.html
Phone: (250) 762-5455
FAX: (250) 762-0244

Hope this helps;
Gregory Gately (K9OYO)
(708) 387-2490
Now 15/16th of the way to being an EXTRA-, this coming April 15th!

Hi,

I have 14 pcs in stock - NOS - but in white boxes - at NOK 115.-
/each. This is about USD 13.70 /each. Shipping from Norway to US
should not be more that $ 5 - 6

Regards,

Arnold Goksyr

DEMOSTENES - N6899 Balestrand, Norway
Tlf. +47 5769 1340 Fax +47 5769 1267
http://demostenes.vestdata.no

Valves, sockets, transformers, books and components
Good stock on all types. We ship worldwide.

>

I'll attempt to shed some light on question #1 with a review of conventional, boring, old-fashioned antenna concepts. This discussion will concentrate on small "electric" dipoles; small "magnetic" dipoles behave similarly except that their equivalent circuits are inductive rather than capacitive.

The "effective area" of an antenna is equal to G*(wavelength squared)/(4*Pi), where G is the directive "gain". For a very small dipole, G is 1.5. Multiply this area by the incident power density and you know how much power is theoretically available from the antenna terminals. This area is much greater than the physical size of the antenna, which causes a lot of confusion even among people who claim to be antenna experts. In practice, only a small amount of the theoretically available power can be delivered to a load because of losses in the antenna system itself, and in the matching system required to transfer maximum power to the desired load. The equivalent circuit of

an electrically small dipole is a large capacitive reactance in series with a small resistance. A matching network (sometimes as simple as a "loading" coil in series with the antenna) is needed to provide a "conjugate match" with the load resistance in order to achieve maximum power transfer. When an antenna is less than 1/100th of a wavelength long, it is very difficult to obtain overall efficiencies of better than 1 per cent, and the efficiency drops off as something between the inverse square and the inverse cube of the physical antenna size. For this reason, very small LF transmitting antennas are usually monopoles (vertical antennas above a ground plane) because the "reflection" of the monopole in the ground creates an effective antenna length that is twice as great as the physical height of the monopole. Antennas are reciprocal devices, so a vertical monopole above ground is also the best choice for a receiving antenna where the objective is to extract as much energy from the incident wave as possible (although I personally prefer loops for normal LF listening, because signal-to-noise ratio is limited by atmospheric and man-made noise picked up by the antenna, rather than by available signal power).

Both the ARRL Handbook and ARRL Antenna Book contain the following two paragraphs, stating the Conjugate Matching Theorem as defined by the National Institute of Standards and Technology (NIST) and applying the theorem to a generic "Transmatch", or antenna matching device:

"If a group of four-terminal networks containing only reactances (or lossless lines) are arranged in tandem to connect a generator to its load, then if at any junction there is a conjugate match of impedances, there will be a conjugate match of impedances at every other junction in the system."

"To paraphrase from the NIST definition, "conjugate match" means that if in one direction from a junction the impedance has the dimensions R + jX, then in the opposite direction the impedance will have the dimensions R -jX. And according to the theorem, when a conjugate match is accomplished at any of the junctions in the system, any reactance appearing at any junction is canceled by an equal and opposite reactance, which also includes any reactance appearing in the load. This reactance cancellation results in a net system reactance of zero, establishing resonance in the entire system. In this resonant condition the generator delivers its maximum available power to the load. This is why an antenna operated away from its natural resonant frequency is tuned to resonance by a Transmatch connected at the input to the transmission line."

The kicker in making an efficient energy sucking antenna is that extremely high Q circuits are required in the Transmatch (or whatever you want to call the gadget used to achieve resonance). By the way, the Transmatch also provides impedance transformation, which is necessary if you want to deliver energy to a load resistor other than one with zero or infinite resistance. Even with very high Q components in the matching network, there are very significant losses from the ground system (in

the case of the vertical monopole) or from any objects in the near field of a small antenna.

Here is a sample calculation of energy capture from a 50 kW, 500 kHz station at 10 km, using "conventional" antenna theory. The effective area of a small dipole at 500 kHz is about 43,000 square meters, and in free space the power density from a 50 kW station at 10 km would be about 0.00004 watts per meter. The theoretical maximum power available from the short dipole is therefore about 1.7 watts. At 500 kHz, the wavelength is 600 meters, and a 1/100th wavelength antenna would be 6 meters (about 20 feet) high. As stated earlier, it is fairly difficult to obtain 1 per cent efficiency with a 1/100 wavelength high antenna _and_ its matching system. That's better than any of my LowFER friends are doing with their 15 meter high transmitting antennas in the 160-190 kHz range. Assuming 1 per cent efficiency, the power delivered to the load in this example would be 17 milliwatts. Not bad; enough to light an LED. With a really high-Q, 20-foot, resonant, energy sucking antenna, this is about the level of perfomance I'd expect. Maybe it's possible to do better, but in no case better than the 1.7 watt limit of a small 100 per cent efficient dipole.

In my opinion, making an antenna part of a high-Q resonator provides no special properties above and beyond fulfilling (at least partially) the circuit requirements for achieving maximum power transfer to the load.

Hi All,
I have a large toroidal core with the number:
AKO3G-5 (symbol) 54620-12K3
The (symbol) looks like a hysteresis curve
or a fat S.
Does anyone know who made it or what material
it might be?

Ok, if it is a constant voltage source, then the voltage is
finite, fixed, and limited from the get go. That's by definition
of what a constant voltage source is.

>> you don't have infinite Q, even if the capacitor and
>> inductor are lossless, because R isn't infinite. The
>> *loaded* Q of the circuit limits the voltage rise to

>
>^ Q *approaches* infinity as RL->infinity, and then Pload->infinity.

Ok, and for a constant voltage source, current through RL approaches
zero as RL approaches infinity. Note that this is just the opposite of
what happens with a constant current source.

>> You don't have infinite time either, you have 1/(2f).
>> After 1/(2f) reradiation begins, and energy is lost by
>> the antenna.
>
>^ The discussion is on the capacitor plate system where far-field

>effects are not being considered (eg: tesla coil).

What does that have to do with frequency? Energy only builds in
the system during a half cycle. The following half cycle the field
collapses and energy is reradiated.

>> Note, if you have a constant voltage source instead of a
>> constant current source, then that obviously limits the
>> voltage rise to less than infinity.
>
>^ Incorrect. The voltage approaches infinity asymtotically
>using a constant voltage source.

Nonsense. By definition the voltage of a constant voltage
source stays fixed, finite, and constant. Only in the case of
an ideal constant current source can the voltage approach
infinity.

>For a current, voltage is only infinite for open circuit.

Correct. For a constant current source, voltage is infinite
for an open circuit. That is *not* true for a constant voltage
source, however.

>> But if it is a perfect
>> constant voltage source (it won't be) then current can
>> rise toward infinity as R tends toward zero.
>
>The example assumes constant voltage source. Also, if RL=0,
>Iload is finite.

Assuming a constant voltage source, then by definition current
goes to infinity as RL goes to zero. This is simple Ohm's Law
stuff.

>> But all real sources are power limited, so there are no
>> infinities. With a constant current source, at some point
>> the current starts to decline because you've run into the
>> voltage limits of the supply. With a constant voltage
>> source, voltage begins to sag as you run into the current
>> limits of the supply.
>
>^ The example is using ideal sources.

Fine. Just make up your mind what you mean by ideal source.
You seem very confused between what is meant by a constant
voltage source and what is meant by a constant current source.
You should also realize that neither actually exists in real systems.

All real systems are power limited. They may have characeristics
of a constant voltage or constant current source at low power
levels, but as you approach the limit conditions, they become
power limited and no longer behave as constant voltage or current

sources. This is true even with ideal components. Real component losses only make matters worse.

I'm not trying to prove that infinite power is
available to R2. My question is still the same:
what is the relative difference in power between
the load resistor for the Fig 2 antenna (R2), versus
the load resistor for the Fig 1 antenna (R1).

If you agree that the power in R2 is greater than the
power in R1, then feel free to design a practical
version of the circuits depicted on the website.
Note that practical considerations cannot be used
to disprove what is shown on http://www.amasci.com/tesla/nearfld1.html
That website only illustrates a basic principle.
If you are certain that the principle itself is
wrong, and that the C2 antenna with the resonator
cannot power its load resistor at a larger Pd than
the C1 antenna which lacks a resonator, then please tell
me where I went wrong, and calculate what the power
in those resistors should be instead.

> Note, if you have a constant voltage source instead of a
> constant current source, then that obviously limits the
> voltage rise to less than infinity.

The power supply depicted on that webpage is a
constant voltage source. Until I see some agreement
that the power in R2 is actually higher than the
power in R1, I am not interested in any other circuits
but the ones depicted.

> But if it is a perfect
> constant voltage source (it won't be) then current can
> rise toward infinity as R tends toward zero.

I am not discussing practical issues. They too easily
end up confusing things. I am discussing the circuit
on http://www.amasci.com/tesla/nearfld1.html which uses

lossless components. If you wish, you can calculate
the settling time of those circuits. I am not
interested in the settling time of an infinite-Q
circuit, or of any other circuits besides the ones
depicted on that webpage.

>
> Well the small stray coupling capacitors of your model
> go away. So your voltage divider analysis is no longer
> valid.

True, but I guess I didn't ask the question clearly
enough. Here is what I'm trying to find out:

If we remove the large metal plates shown on
http://www.amasci.com/tesla/nearfld1.html and
instead use a distant radio transmitter to
power the two circuits, is the power in R2 still
significantly greater than the power in R1? And
is the e-field adjacent to the C2 plates still
significantly greater than the e-field adjacent
to the e-field near C1?

(I assume that we do as before: tune the LC circuit for
maximum power, adjust the value of R1 for maximum
power, then see if we can find values of R2 which
give it a higher power than that in R1.)

> > Doesn't a similar effect arise with EM waves? Or does
> > it only work with the capacitive coupling I've shown?
> > Does the effect vanish if the e-field is part of a
> > propagating EM wave?
>
> If by "effect" you mean conjugate matching,

No, by "effect" I refer to the topic of this thread:
the maximum power achievable by the C2-L2 antenna
being significantly higher than the maximum power
achievable by the C1 antenna. Just so there is no
misunderstanding, "power achievable" means the Pd of
each load resistor. By "effect" I also mean that the
e-field adjacent to the resonator's C2 plates is
significantly higher than the e-field adjacent to the
C1 plates.

> > I'm under the impression that the small resonant antenna

> > And it would "become" even larger at VLF?
>
> That's a backwards way of looking at it.

Are you saying that it's WRONG? If my value of
1/pi wavelengths is incorrect, please tell me what it
should be instead.

I'm not discussing photons. That is a distraction which
can easily obscure these issues rather than illuminate
them. I'm discussing these two simple antennas in term of
EM fields and EM waves. If you believe that EM waves do
not exist, or that for some reason we cannot talk about
them (and must only discuss photons?) then there is little
point to this debate.

I am not yet trying to understand what is going on in my
postulated problem. First things first. I am only
asking a very simple question: what is the maximum power
in R1 and R2 in the circuits shown on
http://www.amasci.com/tesla/nearfld1.html ?

From my reasoning, I conclude that the maximum
power available to R2 in the Fig-2 antenna is MUCH
GREATER than the maximum power available to R1 in
the Fig-1 antenna.

> The effect of this is non trivial, and has a fundamental effect on
bopth the
> antenna, its effective size and I suspect your "problem" with
understanding
> what is going on in your postulated problem.

OK, please feel free to analyze this with impedance
included. Does your improved analysis affect my conclusion?
If not, then my conclusion still stands. I conclude that the
Fig-2 antenna can heat its load resistor far more than
the Fig-1 antenna if the metal plates C2 and C1 are the same
for both, and if all components are adjusted to produce
maximum power.

> I suggest that you get a decent book on antennas and have a read,
antenna
> behaviour analysis does not respond well to simplification unless it
is very
> carefully thought out.

This may be so. That's why I'm here: so that people who
know more than I do can tell me whether R2 CANNOT receive
more power than R1. I claim that it does. If I am wrong,
and if R2 cannot receive any more power than R1, then
please help me correct my mistake by telling me what
the power for R2 and R1 should really be?

Efficiency of a very short antenna system (including matching losses) is
proportional to something between the square and the cube of the
physical antenna size, not the _inverse_ as stated in my earlier post.

Hello Group,
I just purchased a Knight model p-2 SWR meter. I was told that it will handle 1.5kw (which I am not interested in) and that it is good up to 225MHz. I popped off the cover of the RF sensing unit(which is separate from the meter) and noticed that the lead through for the coax is entirely shielded, which says to me that it could accurately measure SWR up to 225MHz. I would like to use this meter for qrp work and accurate measurement of SWR from 1 to 5 watts on HF. It does have a sensitivity pot on the meter, but I cannot drive my TS-520 down that low (or being totally honest, I am not sure how to drive it below 10 watts) in order to test right away. If the meter is not sensitive enough for qrp, is it possible for me to change the resistors or capacitors in the RF sensor or maybe even the main sensitivity pot in the meter? If anybody knows any more information about this power meter, I would love to hear from you!

Tnx es 73 de Paul, KC2DLA

Hi Jim, I found four Burroughs 6844A nixies. They have 13 pins with a gap between pins 1 and 13. The pin circle is 5/8 inch in diameter and the bulb is flat on the bottom, 1 inch in diameter, dome-shaped on the face, with an overall height of 1 inch. We used these in an old vacuum tube computer-scanner and I believe they operated on 150 volts dc with a common cathode dropping resistor. They are yours if interchangeable with the ones your have as I have no use for them. Got anything like ART-13 parts or National HRO parts to trade? 73, John W4THQ

Since this thread is one part of a very heated discussion that
took place earlier on sci.physics.electromag, and since there
seems to be great confusion over this topic, I want to
intentionally limit the discussion to whether
http://www.amasci.com/tesla/nearfld1.html
is correct or not.

Earlier, people seemed to be reasoning that if my EXPLANATION
of this effect was wrong, then the effect must not exist
at all! Also, several made the assertion that the effect
itself (and not just my explanation) violates fundamental
principles of physics and cannot exist. At least, that's what
their messages SEEMED to say.

To eliminate confusion and distractions, I first want to know
whether the stuff on that webpage is somewhat correct. And
to find out if it's an abomination which clearly violates
fundamental rules of physics! :) Once that's somewhat
clear, I'll go back to aruging about the proper explanation
for what's occurring. (Or perhaps drop the topic entirely,
since many people are probably getting sick of it.)

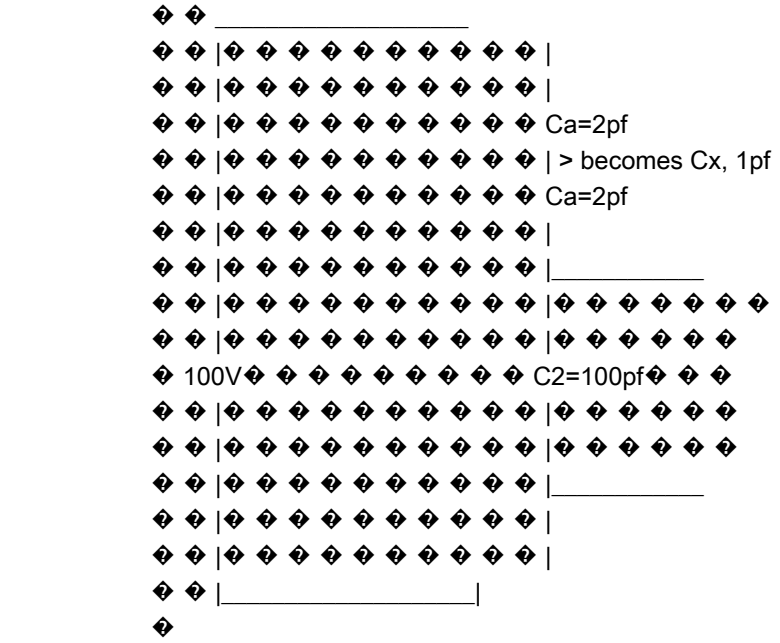
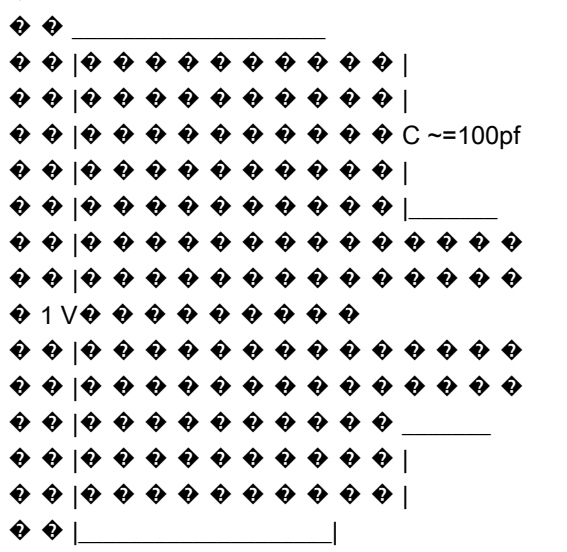
Certainly! Maybe I'm wrong about this and you'll see
the problem.

Cover up L2 and R2 temporarily to remove the
distraction (put them back in the same place later.)
First move one of the Ca capacitors through the power
supply so they are both in series. Then combine them
to form Cx, a 1pf cap.

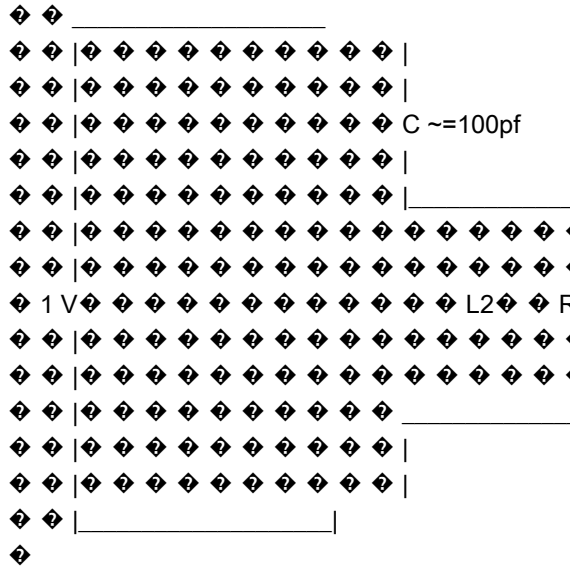


Next, note that Cx and C2 form a 100x capacitive
voltage divider. Thevinenize this, and it becomes a
smaller power supply voltage in series with a single
capacitance. (Hint: it works the same way for

resistive dividers.)



put L2 and R2 back, and there's your series LC circuit.



The power supply becomes 1v, the equivalent series
impedance becomes a single 100pF capacitor. (Or
fairly close to 100, since I'm assuming that
C2 >> Ca.)

If R2 was infinite, the voltage on L2 would
gradually rise forever, and is not limited to 1v
or 100v. If R2 is finite, then it sets a limit
for the voltage across L2-R2, and of course limits
the maximum power attainable. With large
R2, the voltage could become very large,
and in a practical circuit might cause corona,
etc. That is, it could if the real-world Q could

be made that high.

> I just finished with an interesting session with PSpice. I used it to
> simulate the original schematic with the parallel resonant tank circuit. The
> original intent was to look for any evidence of a second, series, resonance.
> There is none.

There is just one resonant FREQUENCY, but the
circuit behaves as a series resonance. Or you
could call it a resonant network, and ignore the
series/parallel considerations entirely, and just
look at its PSPICE behavior.

What would happen if you cover your ceiling with
aluminum foil, then drive it with hundreds of
volts of 500KHz referenced to ground? Small
resonant antennas could run your flashlights!
(Maybe.) Although it might be more sensible
to use the "dual" of this circuit, where a large,
high-current loop antenna has smaller resonant
loop antennas within its diameter. Wrap a
coil around your house. Don't attract the FCC!

Yes, and perhaps you missed the fact that we are
discussing a circuit on a website. We are not discussing
"three capacitors", we are arguing about how a
circuit on a website behaves. Perhaps you came into
the middle of the thread. If so, then the website is
below. If not, then I have no idea what your reasoning
process might be. If you believe that the Ca-C2-Ca
capacitors on that website should be added together...

Perhaps the "extra assumptions" are there because you
never saw the original schematic under discussion?

Now THAT's an interesting sci/cultural topic in itself. Horgan's
"The end of science" presents a directly opposed viewpoint,
and I suspect that many scientist agree with him. And of course
"What Remains..." by Maddox serves as an excellent response.
I wonder how the scientific community divides itself between
these two viewpoints. Is the majority composed of hyper-skeptics
who sneer at "science fiction" possibilities with great disgust?
Or is the majority more along the lines of dreamers who see
that what is not forbidden is required, and that our contemporary
ideas on what is forbidden may possibly be wrong?

Just this week I posted a note to sci.skeptic on this. It's
below. Or search on "horganism." Heh. It describes
recent events here.

Power is equal to V^2/R. The voltage multiplication factor is
proportional to the Q of the circuit, and Q is proportional to R2. When
R2 is increased by a factor of 10, the power also increases by a factor
of 10. Using the PSpice simulation in MicroSim DesignLab with a sweep
range of 1 kHz and 10,000 steps, I get about 300 kV across R2 when its
value is 1000 megohms and 3 megavolts when R2 is increased to 10,000
Megohms. The voltage increase is "compressed" by about 1 per cent at the
higher resistance reading, indicating that the number of steps would
need to be increased to "catch" the resonance peak.

Crackpot antenna theories below! Danger! Mind distortions ahead!

In article <l9jMJTBO3P14Ewm1@jmwa.demon.co.uk>,
John Woodgate <jmw@jmwa.demon.co.uk> wrote:
> inimitably wrote:
> > Maybe you better stop reading my messages for

> juice.

Yep. "Intellectual bullies" need to occasionally encounter victims who don't back down, therefore it's worth continuing the fight... up to a point.

I'm still interested in clearly seeing where I ACTUALLY am wrong in this "energy-sucking" thing. But only a civilized conversation can do this. When opponents seriously believe that an idea can be defeated through ridicule, then there's no possibility of rational thought playing a role.

I'm still stunned at the number of science-types on the newsgroups who apparantly believe that ridicule is an acceptable element in a scientific discussion. If they represent science, give me a crackpot anytime.

ANYWAY, my original "crackpot claim" thought experiment went something like this:

1. EM plane waves are travelling through space.

2. Add an electrically small conductive object, and the waves are only slightly distorted as they pass nearby.

3. Make that object into a resonant antenna with high Q-factor. An enormous local EM field appears, and this field interacts with the incoming waves in the usual way (by superposition), and the sum of the plane waves with the nonradiating quasistatic fields of the nearfield region of the antenna, gives a set of plane waves with much more distorted wavefronts than a similar metallic object could ever give.

Capacitively-driven resonant antenna
http://www.amasci.com/tesla/nearfld1.html

4. Calculate the Poynting vector field, and you find that the energy flux of the incoming plane waves is diving inwards towards the resonant antenna, and leaves a fuzzy "shadow" behind it.

The antenna behaves as if it has grown to about 1/pi wavelength across. Since this only occurs at resonance when the intense local fields are present, it's as if the fields are reaching out throughout the nearfield region and "sucking in" energy from the incoming EM waves. Hence "energy sucking antennas."

At this point, Bilge and others leaped into the fray to defend science against the vile crackpot (me.) I think all of their frantic sword hackings landed only upon science herself. They had to destroy scientific integrity in order to save it, and they did, (except they didn't save it.) A totally shameful thing to behold.

But many days later, while considering somebody's point about reciprocity of absorbers/emitters, I was visualizing the small resonant antenna as a bar-magnet which flips end over end. And I saw my flaw. The quasi-static fields act like a rotating solid object. They are not the source of the "energy sucking" effect at all. The above four points require modification, and the addition of a fifth.

5. The small antenna radiates. (after all, it is generating an intense field.) This sphere-wave radiation superposes upon the incoming plane waves, and if we integrate the amount of field-energy throughout space for many wavelengths around the small antenna, we discover something: The antenna's radiation has reduced the total energy of the purely planar EM waves by superposing with the plane waves in a particular phase.

So, I was WRONG in saying that the quasistatic fields cause energy to be removed from the incoming plane waves. Instead, it is the RADIATION LEAKAGE of some spherewave EM from the tiny antenna which "removes" energy from the original plane waves. A similar thing must occur with a conventional 1/2-wave dipole too. Yes, contrary to what others here say, there are two superposed fields involved: the incoming plane waves and the sphere waves generated by the small resonator/antenna. They sum together, and the result is less energy overall. A 90deg phase relationship is required between the two wavetrains for this to occur.

"Sucking" still occurs. By radiating, the tiny antenna absorbs. Because its radiation causes energy to "vanish" from the EM waves as a whole, that energy must appear within the antenna. And so it does. The resonance voltage grows large, and the load resistor gets very hot, as if the antenna was far larger than it actually is. Momentarily short the antenna, and the resonance energy is dumped, and the "sucking" effect is momentarily halted.

This effect becomes strange at long wavelengths and high Q-factors in the resonators. A tiny resonator can "grab" energy from another one a great distance away, as long as that distance is << than 1/4 wavelength.

This effect, by analogy, can be used to explain how a 0.1nM atom can interact very strongly with 600nM radiation. It VISUALLY explains how

such tiny ammonia atoms can generate such long microwaves in ammonia masers. And, as one physics paper points out, there is even an analogy for stimulated emission hiding in this "resonant antenna" concept. If the phase of the illuminating wave should suddenly shift by 90 degrees, the oscillating resonant antenna will dump energy at a faster rate than if there were no incoming planewaves present. The plane waves can be adjusted to "suck energy" out of the tiny resonator/antenna! The two wavetrains superpose with +90 phase, and the net energy is higher, rather than lower, than with the planewaves alone.

Pretty cool, eh? Atomic physics from the viewpoint of RF engineering. And tiny antennas which, in order to receive a large flow of energy, EMIT a wavetrain of sphere waves.

So I'm *STILL* a vile heretical blasphemer who is going to destroy science, and I'll sway many weak minds with my disgusting propaganda! You can also scare little children to make them behave: if they don't go to bed right right this minute, the PSEUDOSCIENTIST will come and suck out all of your electromagnetic spherewave fluxes!!!

But if you use a frequency like 500 kHz and enough current in the loop
to transmit appreciable power, you WILL attract the FCC. The field
strength outside the loop falls with distance but is far from negligible
even at, say, ten loop widths outside the loop.

I really can't devote time to this sort of extended discussion. A
sceptic who argues that something is impossible because no *known* force
can cause it has adopted a wholly untenable position by implicitly
assuming that we know about all the forces that exist. We can NEVER know
that we have found all of them. The sustainable position is 'Present
scientific knowledge cannot furnish an explanation for psychic powers,
and until such powers can be demonstrated in such a way as to allow a
rational scientific theory to be developed, I choose to assume that no
such powers exist.'

For 'psychic powers', you may substitute 'time travel' (probably) and
several other alleged phenomena.

Most of the critics of your web page don't understand what they are
attempting to discuss, and will never agree with you (or are dissembling
just to provoke arguments), so further discussion is futile. I repeat
that what you claim regarding the two circuits is true, mildly
interesting and has practical applications. It has been known for nearly
100 years.

No.

C2-L2 will reduce down to a two terminal network that looks like
an inductor below resonance and a capacitor above resonance. If the
resonant frequency of L2 and the combined capacitance of the two Ca (1
pf) is higher than the resonant frequency of C2-L2, there's no inductive
reactance seen in series with Ca.

No, not in theory. The basic definition of Q is the ratio of energy stored in the reactances of the resonant circuit to the energy lost per cycle. (Or is that per radian? Oh well, just a scale factor).

It doesn't matter whether the energy is lost to inherent resistances in the components, or is lost to radiation resistance where the components of the circuit act as antennas, or is extracted in a load. All the energy you take out sets the Q of the circuit. The more you take, the lower the Q.

Radio amateurs are too often FOOLS, when you give them some surplus
eqiuipment they start to dissolve the parts, and decide which they
will use and which they won't.
Give them a high quality signal generator, and one week later it
doesn't exist any more
A year later they may decide to build a power supply, and since they
did not save all the parts they must make something simple, while I
prefer to use the units more or less as they come.

If you give them a commercial power supply, they would first remove
all parts, and keep the transformer for later use, and since they
didn't keep the swinging coil (regarded as some rubbish) they have to
use the transformer alone, too high voltage may be a problem, so they
have to look for another transformer...

have some old swinging chokes from 2kW coast station transmitter and
RCA TV-transmitter (2800V anode voltage with 4x 8122)
seems to be very interesting for some friends doing EME (LA8YB & Co),
I was pleased to get rid of it, and they were pleased to get it....

was an article in Radcom about power supplies, and it was described
how - even a small inductor of 20mH could make the 14V 25A psu more
efficient and reduce the inrush current

Seems most amateurs building power supplies are newbies, they wish to
have something simple, every extra component is difficult.

Have used some -30V 2A power supplies with swinging chokes and shunt
regulators for packet radio digitpeaters on QTH's were electricity is
quite unstable. The vltage is stabilized to -24V. The power supplies
are surplus, quite heavy, but useful for this application, somebody
else with less experience wouldn't even dream of using such old
rubbish, even when it is very much room for it.
With swinging chokes you never have a problem of inrush current,
my argument is "use them if you have them" and
such power supplies are sometimes easy to find, I had some at work
more than enough for the 5 or 6 digipeater points I serviced

> collapses and energy is reradiated.

^ Negative. At resonance, power is being delivered from the source over
all the sinewave cycle, because at resonance, the input impedance of
the network is a pure resistance.

>
> >> Note, if you have a constant voltage source instead of a

^ The source voltage stays fixed, but with RL=infinite, the
system has (eg, 1kHz resonance) a double pole at j1000 and a
double pole at -j1000. The output waveform of this system is
thus a sinewave with linearly increasing (ramp-up) envelope
that goes up forever.

^ As RL->0, Rin->infinity because the circuit is an impedance
inverter. Note that for the lower RL (about when Q=3 for the
LC tuned circuit), the resonance effect gets swamped out and
the impedance inversion is no longer true.

2210. "energy-sucking antennas": find my dastardly ploy?

Bilge (root@radioactivex.lebesque-al.net) wrote:

: > Notice that I'm not claiming anything yet. I'm only
: > asking some simple questions.
: >
: Just simple enough to include the obfuscation.

And ***there*** is our problem. I honestly am trying to cut to the heart of our argument, and you apparantly believe my website contains some hidden "gotcha" or some sort of obfuscation. As long as that situation exists, all discussion is pointless. Anything I do will look like a suspicious ploy to you.

So far nobody has found a FATAL flaw in my reasoning on that website. You've stated that http://www.amasci.com/tesla/nearfld1.html contains obfuscation, and unneccesary extra components, but have not said what these are. Why not? Do they disprove my conclusion that an intense e-field appears adjacent to C2? If my website is wrong, and you know the reason, it is a simple matter to state what it is. On the other hand, accusations that are not backed up by explanations look like namecalling. If for some reason you HATE what my website depicts, then that has nothing to do with finding flaws in my reasoning or errors in my conclusions.

Yes, I am trying to prove a point. But at the moment, the point involves only the contents of that website and nothing more. Once it is clear that the e-field near the C2 plates becomes intense, and R2 runs hotter, then we move on to the next simple stage and ask whether a similar thing occurs when both antennas are illuminated by EM waves from a distant transmitter.

If it occurs with EM waves as well, does it prove that my "energy sucking" explanation of small, resonant receiving antennas is right? OBVIOUSLY NOT!

You may believe I'm trying to trick you. Actually, I'm trying to clearly expose my chain of reasoning. If it is sound, then the flaw must be in my explanation, rather than in my assertion that adding a resonant circuit to a short receiving antenna will cause an intense e-field to arise near that antenna, and also will let a load resistor receive immensely higher energy than if the resonator was not there.

: To quote einstein
: "make it as simple as possible, but no simpler". Since all of
: the physics is in the inner stuff, it doesn't seem like you can
: remove the outer plates without eliminating the obfuscatory
: capability of the design.

Yes, this is a very important point. If it's true that R2 gets hotter than R1 as shown on my website, DOES THIS STILL OCCUR if those same antennas are instead illuminated by RF radiation from a distant transmitter? I'm sure that this question has a real answer. (I thought I knew the answer, but since people here are raising such a huge stink about this, and even denying that it occurs, I realized I'd better make sure.)

: > plates C1 or C2. These later can serve as a simplified
: > model of an electrically short dipole antenna, and C1 and
:
: No. By antenna I meant ox cart. sheesh. One capacitor serves that
: purpose. Two does not unless your purpose is to describe two dipoles
: with different dipole moments that are capacitively coupled and then
: pretend it isnt.

My first purpose is to find out if R2 gets hotter than R1 in the situation described on that website. People here have questioned whether it occurs, or even insisted that it does not. If it does occur with nearby metal plates, then next I must ask, does it occur with EM travelling waves? Does a very intense e-field arise near the antenna when a resonator is connected to it? If the answer is yes, then I've clearly shown that "energy-sucking antennas" describes a REAL PHENOMENON. No amount of alternate interpretations will make that phenomeon go away. This of course says nothing at all about whether my explanation is bogus or not.

: > or pursuing implications. I only want to get some agreement
: > that it actually occurs in the setup that I've shown.
: >
: I made it simpler. I let you use any ratio you want. I dont fucking care.
: Use P1 and P2 for christ's sake. jeeez. If that doesnt do it for you
: and this ratio of 100:1 is drop-forged into your skill, I cant help --

My question regards whether R2 gets significantly hotter than R1. The particular ratio is not an issue, unless it turns out to be so low that R2 ISN'T significantly hotter.

: I'm not a brain surgeon. I know when it's time to cut my losses on
: a pointless time sink that's already taken more time from pounding my head
: into the sidewalk than it deserves.

Very well.

: > I can make the results of this thought-experiment be
: > anything I like?
:
: That's why people refer to them as "thought experiments". If you'd
: like limitations, go buy some parts and build a real one.

If all thought experiments are total fantasies, then they have nothing to do with science, and it's amazing that researchers would ever find them useful. What would happen if a patent examiner rode along with a light beam? Nothing! It's useless fantasy.

If you assert that thought experiments can be ignored on the grounds that anybody can create any results which are convenient, then like magic you win the debate. Like magic my website becomes a suspicious ploy meant only to confuse. But I'm not trying to "win," I'm just trying to be heard, and to discuss something which is fascinating to me, and above all to find just where my errors lie. I have no great terror of being proved wrong in public. But it will take far more than "debating tactics" to do this.

If my website is fatally flawed, and no intense e-field appears at the C2 plates, please describe this flaw in simple terms so that even a fool such as I will understand.

In first case, source current is

70Vrms/320k= 219uArms

Total load= sqrt(3.2k^2 + 3.2k^2)= 4.53k

Load volts= 219uA x 4.53k= 1 Vrms

Power R1= 1^2/3.2k = 312.5uW

In the resonant case, the conditions for significant
voltage magnification using resonance are not met.
In particular, Ccoup=1pF or 320k, same as R2. You
should redo the example with R2 >> 320k ohms.

Anyway, we'll assume C2-L1 is resonant. Therefore,

Isource= 70Vrms/(1.414 x 320k) = 155uA.

Power R2= 155uA^2 x 320k = 7.7mW or 24.6 times P(R1).

This is a trivial result because the second case simply
doesn't have the voltage division of the first case.

I have merely created a distortion in the space-time continuum, and the ball-bearing is simply following the shortest path thru space-time :) (a tongue-in-cheek example of gravity).

Anyways, if i attracted the ball-bearing with gravity (by tilting the surface), there's definitely no photons here! (light-switch...OFF).

Bing! A light dawns.

On http://www.amasci.com/tesla/nearfld1.html, the small Ca
coupling capacitances can be combined with the C2 antenna
capacitance to form a Thevenin equivalent circuit with the
power supply. Now the power supply is a voltage source
with a single 100pF capacitance in series, driving an
inductor. In other words, it has become a SERIES
RESONANCE rather than a parallel resonance. I missed
this before.

What happens when an ideal voltage source is connected
to a LC series resonance? The current rises continuously
without limit. And the voltage across the C2 and L2
also rises continuously without limit. WITHOUT LIMIT.
It can immediately exceed the 100V drive voltage if
R2 is a very large value. If we place a small resistor
R2 across L2, the voltage will asymptotically approach
a low level, and the power in R2 will be low. If we
place a very large resistor R2 across L2, then the
voltage will approach a much higher level, and the
power in R2 will be much higher. Or, we could make
L2 part of a stepdown transformer, and convert the
output to whatever current/voltage we desired.
Coolness!

Is this right?

As before, it means that a tiny antenna can intercept
a huge amount of energy if the antenna is a resonator,
and if the Q is ridulously large. Correct? (And yes,
it means that it might take a long time for the
resonance to build up to the final value.

Now HERE'S an interesting thought. The earth's ionosphere is somewhat conductive, causing the earth's atmosphere to behave as a resonant chamber with modes at multiples of approx. 7Hz, called the "Shumann Cavity." This cavity has a resonance at almost exactly 60Hz, and it is accidentally pumped by the continental power grids. (Uh, who decided on the 60Hz standard anyway?) All over the earth there is a weak 60Hz field which is caused by the trapped standing waves of 60Hz EM radiation.

The field is weak, but that means nothing to a high-Q electrically small antenna. Such antennas essentially make their own "high power" fields during the process of signal reception.

What if I build a fairly large superconductor coil a few hundred meters across and attach it to a high voltage capacitor bank... and then tune it to 60Hz? At 60Hz, a quarter wavelength is more than 1000KM. If I allow a really immense resonant voltage to build up across my capacitor, my SC loop antenna will essentially "STEAL POWER" from all the electric companies within 1000KM. And better yet, because of the Schumann cavity, the "antenna" might interact with power grids farther away, and grab energy from them as well! Arrg! Those darned europeans, they settled on 50Hz as a standard. Oh well, I'll just have to draw my megawatts from the USA/Canadian power system.

Once long ago somebody told me that some engineering students in a college dorm had built a device which could extract enough 60Hz energy out of the wiring in the building that it could run a small flashlight bulb. I thought this was totally ridiculous. The ambient b-field in a dorm room doesn't have the energy needed to run a light bulb, no matter WHAT the antenna might look like.

I was wrong.

I wonder if they did something like dunk a big inductor in liquid nitrogen in order to lower the resistance of the copper? Maybe with a large enough inductor (very thick wire, big long core) such cooling would be unnecessary.

Hmmm, what to use as the core? Maybe a big wad of long steel welding rods, to form laminations which eliminate eddy current losses. The longer the core, the better it works, no?

Horrible thought: maybe the power companies are well
aware of this possibility. If my system starts
"broadcasting" an immense b-field at 60Hz, will the
cops automatically appear at my door?

Jeeze, I wasn't aware that actual "supression" was ever
attempted! But it doesn't suprise me. Among physics
educators, belief systems are even stronger than
among fundamentalist christians. You should see the
nastiness that goes on about whether "heat" exists.
Or about the "one true way" to explain how an airfoil
generates lift. Aside from my resonant-antenna flamewar,
we're even seeing a bit of it here when people insist
that fields and EM waves don't really exist, and the One
True Way to explain anything is with photon exchange.

Swift had it right in Gulliver's Travels: the
Lilliputians really do want to eliminate their rivals
over the correct way to crack an egg. The "big-endian"
stuff is deadly serious to some people.

> > Can an electrically small antenna intercept much more
> > energy when it has a resonator, than if it does not? Simple
> > question. And contrary to those who loudly insist that
> > the answer is not interesting, I think that it is.
>
> Yes, it can, and it is mildly interesting.

The contents of those two physics papers are even more
interesting. The one about dipoles supposedly shows
how stimulated emission can be explained from a
wave-based viewpoint. Vile blasphemy which must be
stamped out? If their views are correct, then whenever
an electrically small transmitter antenna is hit by
incoming EM waves of the same frequency and a

particular phase, the antenna EMITS more energy than
it otherwise would.

If true, then when someone claims that stimulated
emission is exclusively a quantum phenomenon which
can only be analyzed in terms of particles... they
are wrong. I doubt this will destroy physics as
we know it. But its always nice to learn something
that isn't already in all the textbooks. It gives
one hope that science isn't at its end, and there
still might lurk some REALLY big things in the
undergrowth.

> > in order to power itself.
>
> That's a leap of faith or wishful thinking.

You misunderstand. If C2-L2 behaves as signal generator,
it is getting its drive right from the power supply
connected to the large metal plates.

What I mean to say is, suppose you were walking around
in a very weak RF field but didn't realize it was there.
If somebody built a high-Q resonant antenna, then
whenever that passive antenna was tuned just right, it
would SEEM to generate an intense signal without using
a power supply. In reality, it extracts energy from
the unobtrusively weak ambient field, and builds up a
huge oscillation.

As for perpetual motion machines, a resonant antenna
could make for a good hoax. For example, if you had

a huge copper coil a few thousand pounds in mass,
and hooked it up to some sort of electrmechanical
resonator such as a rotating permanent magnet... and
then chopped it at 60Hz... you might be able to
extract a tiny amount of power from a mysterious
source, which actually turns out to be the power
lines outside the house, or perhaps the ground-
leakage current from some unbalanced neutral in
the neighborhood. Know any Free Energy devices
which resemble this? :)

in space.

This applies to radio waves too. A 1" metal disk is
almost invisible to 10-meter EM waves, just as a
0.1 nanometer atom is almost invisible to 500nM light.
The uncertainty principle has EVERYTHING to do with
both. Or neither, if you want to think exclusively in
terms of classical fields/waves theory.

I'm not aware that Tesla ever claimed to have any perpetual-
motion inventions. Contact with Mars yes, "Free Energy" no.
His biggest "crackpot" scheme was to flood the entire earth

with 10KHz radiation, then extract significant amounts of
power at great distances without using acres of receiving
antennas. Could this have worked? It all depends on
ionospheric heating losses and leakage to space. And on
the achievable Q's of little bitty resonant loop antennas.

> to the e-field near C1?
>

...then you cant be confused about what happens when they're
removed, unless the intent is antenna legerdemain or you
dont even understand the properties of a capacitor. If
the outer plates are a constant voltage source, remove
them and use wires to the inner plates.

> I'm not discussing photons. That is a distraction which
> can easily obscure these issues rather than illuminate

You arent even discussing E&M. If the photons confuse you,
start with halliday & resnick, and work your way up.

> them. I'm discussing these two simple antennas in term of
> EM fields and EM waves. If you believe that EM waves do

No, you're discussing how you can fool yourself when you're
in over your head. Anyone that believes in photons believes
in E&M waves, in case that isn't obvious for some reason.
It's a real useful way to keep from wandering off into wonderland
and ending up with a ridiculous description of some phenomenon
so that you can return to earth and look for more conventional
explanations before shouting eureka.

> not exist, or that for some reason we cannot talk about
> them (and must only discuss photons?) then there is little

> point to this debate.
>

There's little point anyway. If you cant make the connection
between the wave and particle aspects and have some ability
to switch between descriptions when it is advantageous to
do so, like when one picture provides a vast simplification
over the other, and you clearly cant, then you have no business
discussing anything related to fields.

> of what a constant voltage source is.

Right, but what happens when a constant voltage source
drives a SERIES RESONANT circuit? What happens to
the voltage across the inductor? Does it only rise
to the level of the drive voltage?

I think you'll find that it rises continuously.

My mistake with http://www.amasci.com/tesla/nearfld1.html
was to ignore the fact that the two Ca capacitors and the
C2 capacitor can combine into a Thevenin equivalent
of a single capacitance. This capacitance then appears
IN SERIES with the power supply and with the inductor
as well, while R2 is still across the conductor of
course. It is not a parallel resonant circuit as I
thought. This is what Russell Shaw is talking about.

In a series resonant circuit driven by a constant voltage
source, the series current rises continously, and the
voltage across the capacitor and the inductor rises
continously, even though the voltage across the whole
series resonator remains constant. On my website, the
power supply is 100V. But this does not limit the
voltage across R2. Instead that voltage is limited only
by the q-factor of the circuit as a whole, and the voltage
can be very much higher than 100V

> What does that have to do with frequency? Energy only builds in
> the system during a half cycle. The following half cycle the field
> collapses and energy is reradiated.

You are wrong where resonant circuits are concerned.
Note that I said CIRCUITS. There is no "radiation"
going on, there is only the usual sorts of capacitors,
inductors and resistors. A resonant circuit need not
return all energy back to the power supply on each

cycle. Instead, energy builds up cycle by cycle, and
voltages and currents increase continuously.

> Assuming a constant voltage source, then by definition current
> goes to infinity as RL goes to zero. This is simple Ohm's Law
> stuff.

Apply ohms law to a series-resonant RLC circuit. The results
might amaze you. They're still amazing me.

> Fine. Just make up your mind what you mean by ideal source.
> You seem very confused between what is meant by a constant
> voltage source and what is meant by a constant current source.

No, the problem is miscommunication: Mr. Shaw is assuming
that you are talking about series resonance as he is, while
you are assuming that he is talking about ohm's law applied
to resistors. I suspect that each of you thinks the other
is not only wrong, but willfully ignorant. But its just
miscommunication.

> All real systems are power limited.

Certainly. If it offends you to connect a zero-ohm resistor
to an ideal voltage source, then whenever you see someone
about to do this in their minds... run!!! :)

> RESONANCE rather than a parallel resonance. I missed
> this before.

^ Yes, the input impedance looks like that of a series resonant
circuit.

Note that circuits like this can have more than one mode of operation.

I made a mistake in my last message, making a wrong assumption (tho the
analysis for that given mode should be correct).

In first case, source current is

70Vrms/320k= 219uArms

Total load= sqrt(3.2k^2 + 3.2k^2)= 4.53k

Load volts= 219uA x 4.53k= 1 Vrms

Power R1= 1^2/3.2k = 312.5uW

In the second case, the circuit at a certain resonant frequency is
equivalent to a voltage source of 0.693Vrms driving a series 101pF
cap, a series 1.003mH inductor (for fo=500kHz), and a 31ohm load
resistance. Therefore,

P(R2)= 0.693^2/31 = 15.5mW. Therefore, increase of 49.6 times.

^ How about a very large mass (a pyramid ?) with attached
force transducers to convert low-level/low-freq magnetic
component of an em-wave into mechanical force? By choosing
suitable points for the transducers, a dominant mode of
mechanical resonance can build up, accumulating energy.
Also, choose a mode of resonance such that the base of the
structure is preferentially not moving, to minimize energy
loss into the ground (i don't know if the basic pyramid
shape satisfies this criterion).

I think you missed it because it isn't there in the first place.

The whole point about Thevenin (and Norton) equivalent circuits is that
you can replace one configuration of circuit elements with another, but in order
to be equivalent, the electrical characteristics of the circuits must remain the
same.

In other words, you can have a whole collection of "black boxes" with
any number of equivalent circuits inside them, but unless the electrical
characteristics of any black box can *not* be distinguished from any other box
in the collection, then the internal circuits are *not* equivalent.

Jim

>

It's not unreasonable to assume a geometric picture of E&M. Kaluza
and Klein first tried it in the 1920's except that it didn't pan out
and as of yet, no one has such a model that works. So at the moment,
it's hard to apply the concept to antennas.

>Anyways, if i attracted the ball-bearing with gravity (by tilting the surface),
>there's definitely no photons here! (light-switch...OFF).

Light and radiaation are real (on mass-shell) photons. The fields
corresponding to the static E & B fields are virtual. The magnet
and ball exchange virtual photons. Light bulbs emit real ones.
You can apply the same picture to gravity by picturing the mass as
a sort of gravitational "charge", except that there's only 1 type,
carried by gravitons and the force is always attractive (unless
something is found to fall up).

You can transform one circuit to another equivalent at a *single*
frequency, so that certain impedances are unchanged. For different
frequencies, you have to re-evaluate the transformation.

> generates lift.

Sorry, but you can explain it at many levels, but at the
very lowest level, you're stuck with one explanation -
statistics. It doesnt happen to be the most convenient
way to design a fan, but a new theory of energy sucking
fans has to be in agreement, explain where and why it
differs, or else go figure out where they went wrong.
You cant decide air molecules dont exist because they
dont fit your theory of sending large volumes of "cooling
waves" with a small fan and dont want to use a faster
motor and change the blade shape from that of a large fan.

> that fields and EM waves don't really exist, and the One

> still might lurk some REALLY big things in the
> undergrowth.

Despite the promotion of psuedoscience. Just because you've
been told (by everone in this case) you're wrong doesnt mean
you're ideas are supressed. In this case, it means your
energy sucking antenna is conceptually flawed. So far, everyone
has given you a the reason for getting the numbers you got,
but you are too busy objecting to the explanation to notice they

agreed. Mainly because you aren't interested in agreement unless they'll agree to the way you were going to explain it had they not explained it first. So far, no one has disputed your numbers, they've only explained them such that you're left with a dead end. live with it. If you were being supressed, you wouldn't be reading this. You're being told you're concept is wrong. That's MY idea, and I dont intend to supress it.

Amazing how being wrong is called "supression" as a last resort.

Please look again. In particular, convert the power supply,
the Ca capacitors, and the C2 capacitor into their Thevenin
equivalent. This gives you a power supply with less
voltage and a single series capacitance.

> The whole point about Thevenin (and Norton) equivalent circuits is
that
> you can replace one configuration of circuit elements with another,

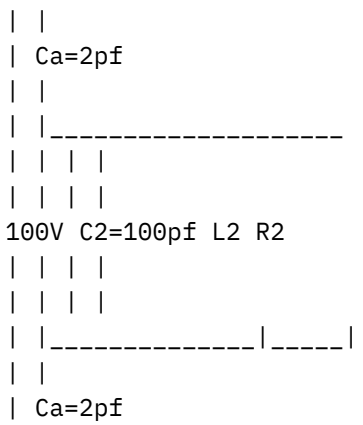
> same.

Hey, I've used them before. A bit. I've only been
an engineer since 1980. But in the digital world,
old courses about RF engineering get pretty fuzzy.

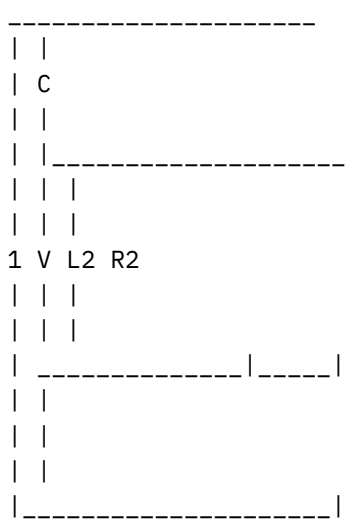
Rather than just talking, go perform the conversion on
that circuit and what happens. You end up with a single
C in series with a power supply of smaller voltage, which
is also in series with L2.

If you cannot do this in your head, here's a crude diagram:

BEFORE:



AFTER:



where C = (2*Ca)||C2 ~= 100pF

See the series-resonant circuit? If not, then
I don't think I can help you.

This may be so, but until I hear you agree to two things,
I can see no point to further discussion. Those two
things are:

1. On the website, the power in R2 is much higher
than the power in R1.

2. On the website, the e-field adjacent to the
C2 plates is much stronger than the e-field adjacent
to the C1 plates.

The reason that I keep harping on these two points is
that I've NOT heard you agree that they are correct.

I've heard you raise all sorts of objections to the
simple contents of the website, stating that there are
unnecessary components present, or that the website is
misleading and obfuscating, or that I can create any
numbers I wish in those two circuits. But you've never
said that yes, in the situation as depicted, if the
components are adjusted for maximum power, the e-field
near C2 is far more intense that that near C1, and the
power in R2 is far higher that the power in R1. Will
admitting that I am right on these two points damage
you in some way? What's the problem?

Others seem willing to continue the discussion, and to
do so without descending into base emotions and turning
themselves into flamers, therefore I shall continue.

> So far, everyone
> has given you a the reason for getting the numbers you got,
> but you are too busy objecting to the explanation to notice they
> agreed.

I very specifically notice that they agreed, but that you
have not. Very very strange.

> If you were being supressed, you wouldn't be reading this.

Ah, I'm a pseudoscientist, therefore I MUST be complaining
about being suppressed. That's what all pseudoscientists
do, right? Those pseudoscientist, they're all the same!
Don't we HATE them! Better not let your daughter marry
one. :)

> Amazing how being wrong is called "supression" as a last resort.

The only "suppression" I see here is your very strange
behavior, as if you wish to shut me up in any way possible,
rather than simply finding the flaw in my website.
You seem to be becoming extremely emotional and have
repeatedly descending into namecalling. Do you lack self
control? Maybe you better stop reading my messages for
awhile.

Power is transferred. The voltage can be anything.
I*V is what matters. Take a piece of coax and put
a BNC "T" at one end and connect it to a signal
generator at the middle of the T and put a shorting
plug on the end of the "T". Measure the voltage
at the injection point and at the open end. Tune
through a resonance "oddly enough, if you cut the
the coax to some length, it will occur where the
frequenct corresponds 4L). Magic, huh?

>> What does that have to do with frequency? Energy only builds in

> You are wrong where resonant circuits are concerned.

No. He is not wrong. He's completely correct.

> Note that I said CIRCUITS. There is no "radiation"
> going on, there is only the usual sorts of capacitors,

There's a field in the capaacitor. As the supply switches polarity,
the charges flow back the other way. Do you have the vaguest
notion of how a capacitor works? Why it has a frequenct dependent
impedance?

> inductors and resistors. A resonant circuit need not
> return all energy back to the power supply on each
> cycle. Instead, energy builds up cycle by cycle, and
> voltages and currents increase continuously.
>

That's called frying your circuitry. The cause is using
conductors that are incapable of returning the charge.
When the wire can no longer carry the current due to
the higher potential differences from the increasing
accumulation of charge, poof. If you put Q in and only
take .5 Q out, the next cycle sees a potential difference

due to 1.5 Q.

> Apply ohms law to a series-resonant RLC circuit. The results

>

It's not a problem, if you treat the resulting infinite current
flow correctly, i.e., you cant use the results to provide detailed
information about a real system. See and proof that 1 = 2, for
why.

Yes, that's true. But have you seen the "equivalent" circuit that
science hobbyist came up with? It's nowhere near equivalent at any frequency.

> thought. This is what Russell Shaw is talking about.

This is simply not possible. There is no way that your three capacitors
can combine into one and then be in series with the inductor.

Please explain, step by step, how you came to this conclusion.

I just finished with an interesting session with PSpice. I used it to
simulate the original schematic with the parallel resonant tank circuit. The
original intent was to look for any evidence of a second, series, resonance.
There is none.

Interestingly enough, the voltage across the tank circuit can rise far
above the value of the generator voltage if the value of R2 is increased to very
large values. It's still a parallel resonant circuit.

The value of R2 sets the "Q" of the tank circuit. As the Q rises with
increased values of R2, the voltage across the tank increases. However, the
power in R2 doesn't rise without limit. There is a value for R2 that maximizes
the voltage across it at the same time that the current through it maximizes the
power. That maximum occurs when the voltage across the tank reaches about 300
Volts and the resistor value is around 1 Meg Ohm.

As soon as I can figure out how to set up the "Optimizer" utility in
PSpice, I'll post the results. If my math skills were better, I'd just write
the equation for the circuit and solve for max power in R2 directly.

Stay tuned for further developments.

Jim

The equivalent capacitance of three capacitors in series is easy to
derive. You can replace three capacitors in series with one equivalent
capacitor with *no* change in the generator voltage required.

> shielded, which says to me that it could accurately measure SWR up to
> 225MHz.

I put mine together in 1966, but if I remember right that's not a shield,
that's the center conductor itself. Note the two solder joints at the
connectors; IIRC the instructions had you wire a small wire into the
SO-239 center pin, then bend it and push the tube on over it, then solder
the wire to the tube.

The readings from mine compare favorably to Bird wattmeter readings and
readings from much more expensive SWR bridges up to 225 MHz. Don't know
if it goes higher.

> said that yes, in the situation as depicted, if the

Because you dont understand what you've even depicted. I'm not
going to let you take an unqualified answer to imply for example
that your idiotic use of external capacitors has any sort of
properties whatsoever as anything out of context, in which case
you cant try and make an analogy out of it. I'm not going to
let you make an analogy from something I didn't say. I specified
exactly what the results would be under what conditions. You
get both or neither. If you cant figure that out, settle for
neither and simply live with it.

That is obviously a troll. Magnetic attraction/repulsion CAN be
explained by exchange of photons, although it is unusual to do that. But
no-one understands gravity and the hypothetical particle that mediates
it, the graviton, remains undiscovered.

Yes, you could do that. The snag, of course is 'superconducting'. You
need a big cooling plant for your coil, and a superconductor that
remains superconducting in the presence of the immense magnetic field
your coil will generate. There are a few practical difficulties like
that which may very well compromise the economics of your fiendish plan!

It is indeed unlikely that one could get enough energy from the field in
a dormitory, even if the application of American wiring rules allowed
the 'go' and 'return' paths to be widely separated. But a split-ring
current transformer attached to the wiring would very likely work.

Unlike the situation just before the turn of the last century, when many eminent scientists thought that all that remained to do was to refine the measurements that confirmed established theories (a view that was overturned completely by Einstein and others in less than 10 years), scientists these days have a much better appreciation of how much we still don't know. It can reliably be estimated to exceed by far what we already know.

For example, we know that quantum entanglement exists, but we have very little idea of how it works and what the implications are. And we don't understand time at all.

I believe that your PSpice model is predicting an upper bound on the
available power because the "measurement" points are not spaced closely
enough in frequency. As the Q increases, it becomes increasingly
important to do the circuit calculations at the _exact_ resonant
frequency. Since there are no other losses in the circuit, there is
nothing to keep the voltage across R2 from increasing without bound as
R2 is made larger.

Measure DC resistance between two needle probes. If less than 1 Megohm
or so throw it away.

Measure inductance of a few or many turns. These modern hand-held
antenna analysers are very good. If it can be tuned to HF then measure
Q at several HF frequencies.

If Q is less than about 150 then don't use it in a tuned power
situation such as a PA tank or antenna tuner.

Quite right, and that equivalence is independent of frequency. So is the
Norton equivalent, which has a current generator in parallel with a
parallel-tuned circuit.

You could do that, but it would not be correct. SH is using Thï¿½venin's
theorem, and it would appear that you are not familiar with it, hence
you will never reach a consensus.

From: af389@lafn.ORG
Message-ID: <38D4FD46.E862EC1B@lafn.org>
Source record: 62386

Sorry for Off-topic, but need you advise from Drake Equipment owners.

I need the email address for the Drake Group List server.

My Drake R4B receiver that has an intermittent Mode Switch.

Cleaning with contact cleaner has never permanenatly cured the need
to rotate the mode switch many times to make the RX perform.

Question is should I repair or sell?

Looks like a major job to replace that multi-deck rotary switch
and realign the receiver. Am I wrong? Are these switches available?

Also have a working T4XB.
Want to find someone who can use these fines radios.
Suggestions are welcome.

PSpice automatically reduces the step sizes during simulation when it
sees any calculated parameter changing rapidly enough to warrant smaller step
sizes.

>Since there are no other losses in the circuit, there is
>nothing to keep the voltage across R2 from increasing without bound as
>R2 is made larger.

Voltage is not power. If you re-read what I wrote above, you will see
that although I found that the *voltage* across the tank increases as R2
increases, that the *power* in R2 first increases, reaches a maximum, and then
begins to decrease as the value of R2 steadily continues to increase.

Three capacitors in series *can* be replaced by one equivalent capacitor
just as three resistors in series can be replaced by one resistor. The only
time my statement would not be correct is when there are other components
connected to the three capacitors.

>SH is using Thï¿½venin's

It is equally hard to reach a consensus when extra assumptions are
presumed even when simple statements are expressed. I'm sure that given three
capacitors connected in series with no other components that you could calculate
the value of a single capacitor that would be equivalent. That's what I said in
the original statement.

If the two circuits are equivalent, then it should be easy to derive the component values for the series-resonant circuit that would make it equivalent to the parallel-resonant original. I'm sure it would only take you a few minutes. Could you post your results here for me to study?

It would be easier for me to see what's going on if the values were expressed so that there were no negative values, -10mH for example, or values that include square roots of -1.

Find an electronics parts distributor that carries DeoxIT. Pop the $20 or so for the teeny little bottle and use it on the switch wafers. It may not be a permanent cure, but it's certain to do a better job than most contact cleaners.

You can pre-treat with the spray DeoxIT, but you want the expensive teeny bottle of 100% stuff (commonly available spray is 5%, there's a 100% spray but better to use the skinny tube with the teeny bottle).

It looks expensive, but I've treated nearly every bad contact I've had other than cold solder joints with it, and I bought my bottle in 1995, and have about 1/4 bottle left.

I was wrong about the pyramid bit, power would be lost into the
ground. Only a suspended mass in space (or on suitable supports)
would be low loss.

It gives the equivalent impedance which is what is important for
calculating the input power at or near resonance. It is also a true
series-resonant input impedance behaviour.

In first case, source current is

70Vrms/320k= 219uArms

Total load= sqrt(3.2k^2 + 3.2k^2)= 4.53k

Load volts= 219uA x 4.53k= 1 Vrms

Power R1= 1^2/3.2k = 312.5uW

In the second case, the circuit at a certain resonant frequency is
equivalent to a voltage source of 0.693Vrms driving a series 101pF
cap, a series 1.003mH inductor (for fo=500kHz), and a 31ohm load
resistance. Therefore,

P(R2)= 0.693^2/31 = 15.5mW. Therefore, increase of 49.6 times.

As it happens, if you impact a beam of photons (single freq laser) on
a single slit, the interference pattern will be visible on a projection
plate, with bands predicted by the 2D fourier transform of the metal slit
structure.

If you reduce the beam to one photon at a time, and repeat the strikes many
times over, the probability density of strikes on the projection screen still
produces the banded structure!

People have wondered how this can happen when its supposed to be an *interference*
pattern, but what other photons can the single photons interfere with?

This has lead to some people postulating alternate dimensions/universes/timelines
are supplying the extra photons momentarily.

It could also simply mean that one should consider space-time as an analogy to
time-wave/frequency-wave fourier duality. IE: If one tries to pinpoint small
matter to a definite position, the time that it is there becomes uncertain. The
time therefore becomes broad-band as the positional accuracy is made narrow-band,
which is quite obvious when one figures out the fourier space/time duality
implications of our universe.

As for the magnet pulls ball-bearing trick, i know all about quantum level energy
transfer, but when considering macroscopic continuous problems such as LC resonance
and antenna capture area, quantum effects are not neccessary.

And along with that is the knowledge that if it were simple, it
would have been done. So, it's usually a good idea to exaust the
conventional explanations first. Most experimental anomalies are
anomalies in understanding the data, not anomalies that represent
new phenomena. Only after all other explanations are exausted,
is it time to consider new ones.

>C2 >> Ca.)

OK. I see it now. I'm a lot more comfortable with pictures than with
words.

However, the Theveninzed circuit is still not series resonant! Voltage
sources can be replaced by zero Ohm short circuits in order to calculate circuit
characteristics. As far as the inductor and load resistor can tell, there is
still an effective 100 pF cap across them in parallel.

>There is just one resonant FREQUENCY, but the
>circuit behaves as a series resonance. Or you
>could call it a resonant network, and ignore the
>series/parallel considerations entirely, and just
>look at its PSPICE behavior.

The circuit behaves as a parallel resonant circuit since all the elements are effectively in parallel. The circuit would behave as a series circuit if the load resistance happened to be in series with the inductor or the capacitor instead.

In any event, the response of the circuit would be the same no matter what name we use to describe it or which Thevenin incarnation we use. PSpice analysis shows that the voltage across the load resistor can increase without limit as the load resistor's value increases. I originally thought that PSpice analysis also showed that there is a finite, non-zero and non-infinite, value of the load resistor that results in maximum power in the resistor. Subsequent simulations showed that the power *does* increase without limit. A value of 100 Meg Ohms for R2 resulted in a power of over 20 Watts!

and if you wish to test how many turns you need for 50 ohm on the
lowest frequency, use a 6BQ5 valve power generator to check heating of
the core and winding, can send the circuit if some interest. Advantage
with this valve type oscillator is that it will survive different
loads without any precautions taken

yes, G3SEK has one such application in his book
"The VHF/UHF dx book" see http://www.ifwtech.demon.co.uk/g3sek/
it is a simple circuit to read linearly from 1mV RMS up to 3V,
has the following ranges: 0.1/0.3/1.0/3.0V FSD with +/-2% linearity
across the entire range, "this is good enough to justify the use of
3 1/2 digit LCD panel meter module as an alternative to the analogue
meter shown" (page 12-5 and 12-6)
the circuit consists of a matched pair of schottky diodes and a TL072
or TL082

>So while there may not be a lot of reason for a better AM detector,
>the process of exploring alternatives to the simple diode detectors
>may have value that can't be defined.

> Michael VE2BVW

have been told that the typical ex-German Audion type detector used
with zero biassed pentode has similar effect of pulling a weak AM
signal out the back groundnoise. Audion type detectors seems to have
vanished from most applications in the 20's, while it seems to be
reinvented by the Telefunken (Germany) in 1936.... at a time when
everybody else was only thinking of making efficient receivers with
AGC as well as audio derived from a diode detector.

A second session with PSpice this afternoon showed me similar results to
the ones you got. I guess I shouldn't be simulating at 3 AM if I'm going to be
posting the results.

Short version... The power in R2 goes up as its resistance goes up. The
100:1 ratio shown on the web site is very conservative.

Before I go to the effort, is this going to be a semantics game
because wavefunction isnt called particle function or some other
such nonsense? If so, the answer is no. If, on the other hand,
this is a legitimate question, fine, but I've wasted enough time
with providing answers to non-questions that really didn't want
an explanation. I'm not going to repeat the 150 line episode I
just was stupid enough to get suckered into by believing an
explanation for this energy sucking nonsense was the goal in
this energy sucking. If you plan to object to a particle being
a probability distribution, a semantics newsgroup will be
a better place to ask.

>
>People have wondered how this can happen when its supposed to be an *interference*
>pattern, but what other photons can the single photons interfere with?
>
It's not necessary to refer to the resulting pattern as interfereence
in the classical sense. By definition, classical interference involves
waves. If instead, you look at the photons as as accumulating according
to the probablility distribution defined by their wavefunctions, then
you end up without needing photons to interact with each other, since
they don't anyway. In addition, since you cant simultaneously determine
the number of photons and their phases, they only way "interference" can
occur is if the sources are indistinguishable. When the sources are
indistingushable, you aagain can use the simple picture on one photon
at a time, but the wave fumction, and therefore the probability of
where it will land on the screen is modified by the possible paths the
photon may take. The superposition must be coherent superposition, because
the probabilities of traversing each path are not independent of each other.

>
>As for the magnet pulls ball-bearing trick, i know all about quantum level energy
>transfer, but when considering macroscopic continuous problems such as LC resonance
>and antenna capture area, quantum effects are not neccessary.
>

No, and those pictures are usually inconvenient for macroscopic phenomena,
too. However, if some explanation cant be reconciled with those pictures,
usually there is a problem with the explanation. If someone were to claim
they are able to collect more energy than is radiated into the solid angle
they have available to collect the energy with, then it's perfectly reasonable
to cosider a flux of particles and (I'm assuming a 1/r potential, as in E&M)
ask why an isotropic distribution is no longer isotropic. Any claims of
"distorting space" are equivalent to a force on those particles and since
in the case of an antenna, the electrical components dont change the
geometry you see (which, since seeing is also electromagentic in origin,
you would expect to be able to do something similar same thing at optical
frequencies), you'd have to interperet the additional flux as a result
of a force. Furthermore, since I can always define a uniform flux that
crosses the surface of a sphere defined by a radius r in a time t+/-\delta t
as allowed by the uncertainty principle, placing an antenna at some distance
r that collects more energy than it's area allows, requires the either
the additional energy to travel faster than light, since it's path must
be longer or violate causality by requiring the source to alter it's
radiation pattern in anticipation of it being placed in some location.
Neeither of these are as easily visualized using a wave picture, but

because the wave and particle pictures have to have sensible pictures
in terms of each other, it's a good way to rule out the "energy sucking"
crap. If this energy sucking were true, RADAR would be useless, becuase
I could connect a choke and tuning cap to my plane to make it a stealth
bomber by doing the opposite and make myself "electrically smaller" or
take a balloon and throw out a bunch of little resonant circuits that
magically cover the sky by being "electrically bigger" than the
tin foil surroinding them. Anybody willing to throw a tank circuit
out the car window that's "electrically big" to fool the RADAR? I
guessing the answer is no.

2270. 1st project for young hams: move cheap walkie talkies to 6 meters AM

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-20 00:00:00 UTC
From: wa2ise@netcom.com
Message-ID: <8b4eeh$3r6$1@nntp9.atl.mindspring.net>
Source record: 62225

Modifying toy 49MHz walkie talkies for 6 meters:

For some super cheap local comm work, modify 2 or more of
those cheap AM superregenative 49MHz walkie talkies
Radio shack or KB or other toy stores sell for less than $10
a piece. I found a quantity of surplus crystals at 50.374 MHz
for 79 cents each. These particular ones look like TO3
transistors, but they fit in the talkies. Of course, try out the
talkies before mods are done. Then replace the 49MHz
crystal with the new 6 meter crystal. Then using a real 6
meter rig receiver tuned to the new crystal frequency or a
counter, adjust the variable inductance coil while transmitting
with the talkie. See pictures to see what this coil usually
looks like. You'll probably move the slug to less inductance
(outwards from coil body). I used the above mentioned
crystal as it puts me into the "all mode" subband, where AM
is proper. Be sure to mark the modified talkies as ham rigs,
and only let hams use them.

This could be a simple and fun project for boy scouts getting
their tech ham tickets. Gets them something cheap to practice
modifying, and something they can do some QRP work with.

Pictures are at the bottom of the web page:

>Pass. As I say, from a distance it sort of looks OK.

Good choice, since the relative capacitance doesnt determine
the fields uniquely and the drawing lacks enouggh information
to make a definitive statement about them. I predict that
as the plot unfolds, the physics constraining the capacitance,
plate geometry and fields will be a casualty of the legerdemain
and buried in the initial "reasonableness" of how large the
fields are, since it isnt reasonable to say much at all.

billb@eskimo.com (William Beaty) writes:

> By radiating, the tiny antenna absorbs. Because
>its radiation causes energy to "vanish" from the EM waves as a whole, that
>energy must appear within the antenna.

Scattering theory states that the elastic cross-section is at least
as large as the inelastic cross-section. In other words: the antenna
must scatter (divert into new directions) at least as much energy as
it absorbs from the plane wave.

It is possible to make an electrically small, resonant reflector,
which scatters a lot of energy but does not absorb anything. But
you cannot do the opposite.

Also, the energy balance is determined by the phase of the scattered
waves in the forward direction, because it's only there that destructive
interference can remove energy from the incoming wave.

For more information, search for "Optical theorem" in physics books.

>I'm still interested in clearly seeing where I ACTUALLY am wrong in this
>"energy-sucking" thing.

If it violates conservation of energy, it's wrong. That's as far as I would worry it through, personally.

Like some other posters mentioned, if you push simplified, algebraic, circuit theroy too far, you need a mathematician familiar with things like infinities multiplied by infinities to explain the inconsistancies - not the usual drill for design EE's.

When possible, I stick to equations that don't produce mathematically bizzare results. If a bizzare result crops up, I try to use a different form of math, and verify the form works by comparing to bench test measurements. A no-brainer approach, I suppose, but if producing useful circuits is really your goal...

Get a ARRL Handbook from a ham or a hamfest. Pick a year to suit your
requirements. Pre 1970 gives you lots of tube circuits and post 1980 lots of
solid state circuits and construction info.

2283. Re: Toroid Core Identification?

There's also the possibility that it's a tape-wound core. The logo sounds like Magnetics, Inc., to me, and IIRC, they used to make tape cores. In that event, it could be useful for making an audio-frequency transformer (e.g., a transformer for a relatively low-frequency switching supply). Tape wound cores are commonly encased and look a bit different from ferrite and powdered iron cores.

Cheers,
Tom

You'd best be careful about the signal quality on the 'Talkie
you use. I had an old pair of Knight Kit walkie-talkies that
I built when I was a kid in the early 60's. They were on CB
channel 7, and I had a *blast* with them. Well, I pulled them
out for my kids a few years ago, and found out that they trash
the *entire* set of CB channels when transmitting. The newer
49MHz talkies may not be any cleaner than the ones I had.

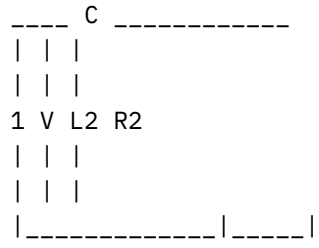
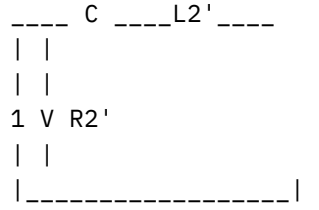
James Meyer wrote:

> > See the series-resonant circuit?
> Well, one of us definitely needs help.



You can take this one step further.
If we restrict ourselves to a single frequency, the
impedance
created by the parallel L2, R2 can also be created by a
series
L2' and R2' (not necessarily the same values as L2, R2).

So the circuit can be redrawn as



Now the series circuit (which is easier for me to
understand) is apparent.

If you change frequencies, you may need different R2',L2'

Opinions expressed herein are my own and may not represent those of my employer.

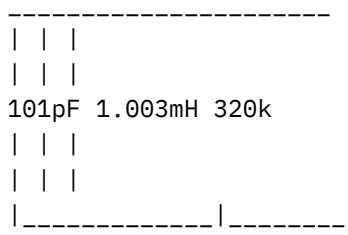
The circuit above isn't the same as the one we've been discussing. The
original circuit was fed with a voltage source. A voltage source is a zero
impedance component. For AC impedance analysis, you can replace voltage sources
with short circuits. When you do that, you get this:

>--+------------------+
| |
| | C=101pf
| |
| |_________________________
| | |
| | |
| 1.003mH 320k
_____________	________
>-+-----------------+

That can be re-drawn like this:



Now it looks like a parallel resonant circuit to me.

2295. Better estimates of inductance for few-turn coils?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-20 00:00:00 UTC
From: davem@cs.ubc.ca
Message-ID: <8b66t8dha1@newcastle.cs.ubc.ca>
Source record: 62250

I originally posted this in sci.electronics.components, but it occured to me I might get a better answer here. This is a composite of two postings in that group:

I'm trying to model the low-pass filter at the output of a VHF transmitter. It uses 3 inductors in series and 4 capacitors in shunt. I know the capacitor values, but I only know the physical measurements of the inductors, not their inductance. I need that to model the filter.

The inductors are actually 2.5 turns of 0.050 inch diameter wire (probably 16 AWG magnet wire) close-wound. Two of them have a diameter of approximately 0.280 inch (measured from the centre of the wire) while the other is 0.300 diameter. Their identification in the parts list is LE-300 and LE-185 respectively, which means nothing to me.

The standard (d^2 * n^2)/(18*d + 40*l) formula for single-layer coils predicts inductances of 50 and 55 nH. However, the books also note that the formula isn't very accurate if the coil length is smaller than its diameter.

The ARRL Handbook has a graph of real measured inductance for a particular range of coils, and it demonstrates that actual inductance can be substantially higher than predicted by formula. A 2.5 turn coil had a measured inductance about 10% higher than its calculated inductance, but this is spaced-wound not close-wound and a different diameter than mine, so it's not clear how applicable that factor is in my case.

Is there a more accurate formula for the inductance of coils of only a few turns, whose diameter is greater than their length?

+++++

Some more details of the situation: Someone has donated a number of commercial FM transceivers, originally designed for 150-174 MHz operation, to our amateur club. The firmware in the radio will happily tune to 144-148 MHz, but the power amplifier needs some changes to be efficient at that frequency. A technician somewhere long ago worked out the set of changes that are supposedly needed, but isn't around to ask any questions of. I've been looking at the "official" change instructions, trying to understand them. Some of the changes are just adjusting impedances in base and collector circuits of the power transistors - adding capacitance here, reducing or increasing inductance there. These make sense as simple impedance matching, and show measurable changes in output power vs. frequency that are in the right direction.

But one part of the modification suggests adding capacitance to 2 of the 4 capacitors in the output filter, and spreading the turns of the inductors apart. This doesn't seem to make sense to me - altering only some of the components of a 7-pole filter isn't just going to change its cutoff frequency, it will also change the shape of the passband. And spreading the coils will reduce inductance, *raising* the cutoff frequency - the opposite of what should be desired in this situation.

That's why I want to model the filter - to get some idea of what the response was designed to be, and how these changes will alter it.

Dave

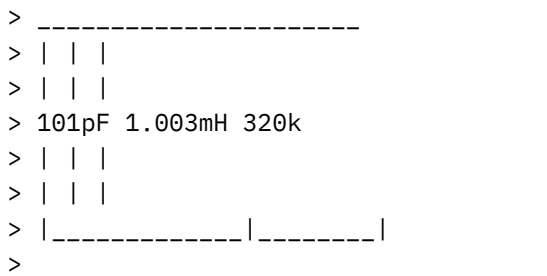
That can be re-drawn like this:



Now it looks like a parallel resonant circuit to me.
(Where has the voltage source gone now? No, don't bother....)

It can equally well be regarded as either. The argument is futile. All
you must do is to retain one or other interpretation throughout one
chain of reasoning. You can't change horses in mid-stream.

I think you need to reconsider that conclusion, if you think that it
implies non-resonant behaviour, because it is inconsistent with the
Thï¿½venin analysis. In the case in point, your conditions are satisfied,
since Ca = 1 pF and C2 = 100 pF. But the circuit undoubtedly does
resonate.

I'm designing a 12V 5A linear PS for an HT and I want to put in an overvoltage crowbar that is somewhat similar to a design in the 1997 ARRL Handbook. I'd prefer to shop as few vendors as possible, and Maxim has been easy to do business with. One chip of theirs, the MAX8212, seems to fit my needs.

Any comments, pro or con? What do the data sheets *not* say that might bite me?

Take care,

Dave

Do photons have mass?

Not that anyone can measure. The upper limits to the photon mass range from 10^-40 to 10^-60 grams depending on the method used. All methods compare Maxwell's equations for a massless photon with one including a mass, and then examine many different electrodynamic systems in the universe at larger and larger scales to search for deviations. None have ever been found, and the scale of the system, from Heisenberg's Uncertainty Principle, essentially sets the upper limit to the maximum mass allowable by the test.

As far as solar sailing a better question might be whether photons can exert pressure. There is quite a bit of evidence to support the claim that they indeed can. In fact many argue that the pressure exerted by photons are instrumental in describing some of the physics taking place in newly formed stars which might otherwise collapse back into themselves were it not the for the internal photon pressure acting upon them.

2304. Re: Better estimates of inductance for few-turn coils?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-21 00:00:00 UTC
From: Tom Bruhns <tom_bruhns@agilent.com>
Message-ID: <38D7DBDE.8782E1FF@agilent.com>
Source record: 62146

For what it's worth, using a presumably more accurate formula, I got
0.0497uH and 0.0553uH for the two coil sizes. That's certainly within
engineering tolerance of the values you got. A number of years ago, I
ran a comparison of the classic formula you quoted and some presumably
very accurate tables+formulas in Grover's "Inductance Calculations"
book. The differences were so small at all practical D/L ratios that
I've simply put the much more complex calcs out of my mind; as I recall,
the worst case was about a 5% error for extremely short coils, and about
8% for exceptionally long coils. It seemed to me that any RF coils I
was likely to be involved with would be within 3%. However, that does
NOT include inductance of the leads, but ONLY the coil itself. And it
assumes the coil is in free air; if the coil is shielded, its inductance
will be significantly lower than the formula predicts, and even if it's
just close to a shield on one side, the inductance will be somewhat
reduced.

There's also a freeware (essentially) program on
www.saratogasoftware.com that's useful for calculating inductance of
coils. It deals only in integral numbers of turns (not unreasonable to
me; somehow that half-turn has to be completed...) and gives for the
0.3" coil 35.9nH at 2 turns and 67.5 at 3 turns; 32.3 and 60.4 for the
0.28" coil.

Cheers,
Tom

Hi all,

I have just ordered a PK-3 keyer board and parts from morsex which I plan to build and mount in an altoids box. My question is about what would be the best way to keep the small pc board suspended above the bottom of the altoids tin. In a commercial kit they often use little sockets that you screw the board into but what do you savvy homebrewing types like to use as standoffs.

Thanks please post the reply here so that others may benift!

There's a simple DOS beacon message generator program on my web page.
Although it was not really designed to be a keyboard program, it will
function as a very basic Morse keyer. Diagrams for PC to rig interfaces
using either the serial or parallel port are included on the web page.
My program will _not_ run under Windows; for that you will need to
search the web for something more modern. For example, check out CwType
at http://www.dxsoft.com/micwtype.htm

Hi All,

I am in desperate need of a schematic and parts list w/ numbers for the
Agrelo DFJr. antenna array. The J. Agrelo story is just too painful so I'll
spare you the details.
Thanks to Steve, WA3SWS for the info he sent me.
This unit had RF applied to the RX port and the little rx amps are blown.
Looking for those parts numbers.

Any and ALL help is greatly appreciated!

The easiest thing I can think of is 4 small nylon screws and 12 nylon nuts. Drill the holes in the corners of the circuit boards (or buy smaller nylon screws), and drill holes in the altoid box. run the nylon screws up through the bottom and fasten with a nylon nut. Put another nylon nut on the screw at the correct height you need for a standoff, put in the circuit board, and lock it down with a nylon nut. you will then have adjustable standoffs that also serves as "feet" for the bottom of the altoid box.

you might measure it, and when you apply it in a circuit you may
discover that it is a different value, still you need the formulas to
decide the actual valiues - in practice

sorry, I believed you understood English over in America(???) ... in
an international newsgroup... believe a quarterwave RG213 identical to
1/4 wavelength long piece of coax?

Those of you who have some practical experience will be aware that
some mismatch may appear on the frequency you wish to pass.
So dependent on the application, this may be a problem, sometimes not,
but usually one wish to avoid attenuation on 144MHz

>the *entire* set of CB channels when transmitting. The newer
>49MHz talkies may not be any cleaner than the ones I had.
>
I checked them for this, they're not bad. Wouldn't drive a linear
with them though. The modern versions must be a better design than
the old CB ones years ago. Oh, yeah, you can hear one of these talkies
in receive mode; superregenetive sets emit some noise in receive.
I have what the package claims "4 Transistor design", per unit.

Yes. The only reason for the confusion is a refusal to take quantum
mechanics seriously. In order to get trapped into needing to justify
long wavelengths emitted from point sources, you first have to believe
the photon has a size in some geometric sense which isn't compatible
with being massless, just for starters, rather than calling it's size
the region in space you are most likely to find it. If you take the
probabalistic viewpoint of QM as a description of nature and don't
need to put everything in terms of something you can see, you're better
off. Unfortunately, cconvenient usage of an analogy in a particular
context often ends up being taken as fact.

>everything that is happening between the microphone and the antenna .

Aw, Come on guys, this can't be that hard! Let's think outside the
box we imprisoned ourselves in.

In any radio transmitter, you must first generate a radio-frequency
(RF) electrical signal, with sufficient power to generate radio waves
when it is applied to the antenna. An "oscillator" is the device that
generates the electrical signal, and "amplifiers" boost it to a level
that the antenna can broadcast. This signal provides the energy that
will carry the information or "modulation" (i.e., your voice) and can
be distinctly tuned by the receiver on the other end of the
communication. How the antenna converts RF electrical signals to
become RF radio waves is pure magic (and I'd like to hear an
explanation of that myself).

Modulation is the means of modifying the RF electrical signal by tiny
amounts that relate in some way to the input signal. In your example,
the input signal is sound , which the microphone converts from
pressure waves to electrical "audio" signals. These tiny electrical
signals are amplified and then allowed to modify the original RF
electrical signal. Regardless of how this is done (analog AM, analog
FM, or digital) the modulator varies the waveform in such a way that
the receiver on the other side of the planet can "de-modulate" it and
recover the original information (i.e., your voice).

There, that wasn't so hard, was it?

regards,
monty N5FC

I really thought someone would have said by now that whether an impedance
measurement port looks like a series resonance or parrallel resonance, is
determined where abouts in the circuit the measurement is done. After all,
the circuit is an impedance inverter, so (series resonance)<->(parrallel resonance).

Hi all, I'd like to build a home brew power supply w/
2 to 30 V out , 3 Amp , run on 120VAC.

A friend said that QST has had articles before on this
type on project kit, but I don't have a sub. to QST mag.

If someone has a higher volt and amp output, that would
be great too.

thanks for any help
Ed , engai@sprintmail.com

Hi,
for Filtering ... I've always made a 4 diode bridge rectifier
from 1N4001,2,3 and some caps. Even if 1 had a wall transformer
that's suppose to be regulated, I've found that if I can't hurt,
and some caps. 0.1uF and 0.01uF .

voltage regulation ... 7805 = 5volts ? or what ever the device
needs as for volts in.

I had a chief engineer at KOEL who was of the opinion that there was no problem that couldn't be mitigated by adding more capacitance. By the time I had left the radio station, Arnie had wired in so much capacitance into virtually EVERYthing, that it would take a half hour from the time I pulled the switch, just for things to finally shut off.

The downside of that was that I could make a fresh pot of coffee between the time I pulled the switch in the morning, and the moment when the board finally came on.

But not even the Simon and Garfunkel records hummed.

2332. Hickok tube tester Compactron Adaptor wanted

Hello group, has anyone the compactron adaptor, Hickok part # 1704
that they can part with reasonably ?

This allows you to plug into the TV-7 tester tubes like 6LF6, 6JE6C, etc.

I will pay 20 dollars delivered to New Jersey for a good,
completely working one.
I had found one last month but it arrived broken and worthless.

Please respond privately if available.

Regards,
Joe Pratt, Tubecntral@aol.com

Since I dont have pspice, I have to use the old-fashioned method known
as laziness, meaning jackson is overkill and the default is halliday &
resnick level, since it fits the situation and nothing more complex
should be required.

As long as the geometry remains fixed, it really doesn't matter -
it's a black box. In any case, the fields arent defined by the black
box. The only case in that you can simplify this is to use ideal
capacitors with no resistors or inductors and then, the field is the
same everywhere. As I said earlier, one may choose components to get
most anything, but it didn't seem to register. More is needed to
specify the fields. I can get a 100 pf cap by choosing A/d in an
infinite numer of ways. The capacitance determines the charge at a
given potential, not the fields. The geometry alone determines the
capacitance, but the capacitance doesnt specify the geometry. The
fields require that the voltage and geometry of the charge desnisty
be specified completely (unless you want to specify the normal
derivative everywhere instead of V or unless you are really into
pain and specify part of it one way and part another).

For the ideal case, only the pieces immediately above an below the
inner capacitor contribute to the the series piece that is denoted
-||--||--||-- and the rest of the area is an effective parallel
capacitance. It will be obvious the outer capacitor is totally
without puropose. Take the capacitors such that their midlines may
have some offset denoted by off (i.e., it isn't symmettic vertically).
Then:

```
--------------+
|
-----------------------
===

-----------------------
|
--------------+
```

separation of outer = do, area = Ao,
separation of inner = di, area = Ai
separation center-to-center = off

It's equal to:

A1 A2 A3 A1+A2+A3 = Ao, A2=Ai
-------+-----------+----------------+
| | |
------- --- ---------------
===
+ +
------- --- ---------------
| | |
------ +-----------+----------------+

Since A1 and A3 are just the total area - A2, I can wirite it more usefully as (w/o \epsilon_{0}, too)

(A-A2)/do + A2/do

The value of the capacitors in series then must be just A2/do, the total separation of the large plates (which shouldn't be too surprising since the inner plates are not doing anything yet):

(omitting \epsilon)

1/C = [(do - di)/2 - off]/A2 < outer-inner (top)
+ di/A2 < inner-inner (inner cap)
+ [(do - di)/2 + off]/A2 < inner-outer (bottom)
= (1/A2) [(do-di) + di]
= do/A2

and you get C = A2/do for the effective capacitance regardless of how you choose the geometry For a voltage maintained on the outer plates, you have a total charge density:

\sigma = Q/A2 = CV/A2 = \epsilon * V/do

If you add a resistor to the center, then at time t=0, the fields are still the same, everywhere, but the charge is bled off across the resistor until the plates are equipotentials. So the field between them is 0 and the field outside is larger. Suppose you reverse the field on the outer plates after 1/4 of the charge bleeds off? Then the outer plates are driven to -V and V, but there is still charge on the inner plates and the capacitance hasn't changed,

Q ------------- -------------
+ - from V

_ (induced) -> + (induced) _ (remaining)
.75 Q --- ---
+ "" - "" ""

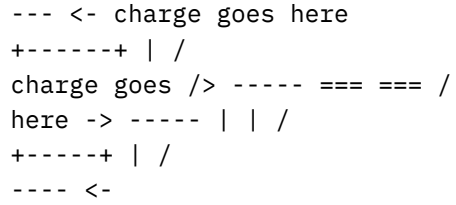
The +Q induced - _ Q left over, leaves only -.25 Q

It's possible to arrange R, C, A, d so that the relative field strengths can be either larger between the inner plates or between the outer and inner plates, or in the case of vertical asymmety, the inner plates

can have a field value that lies between the other two values.

The outer capacitor, as I've mentioned repeatedly serves absolutely no purpose. All it does is a job that two wires would do better and with a simpler analysis. I still have no intention of getting suckered into agreeing to the results of an incompletely specified problem. So far, almost nothing is specified that is of any use to the question posed.

>
> Now it looks like a parallel resonant circuit to me.
>



What's the difference? Nada. Charge is supplied to the same plates and induces the charge on the same two plates in the other cap. Call it anything you like - they dont do anything but act as wires here, since anything you can do with them, you can do without them.

Yes, that's how they are generated. WB is referring to the fact that
efficient radiation normally requires the radiating body to be at least
as large as the wavelength of the emission. But I'm not sure that it
applies when the body is of atomic dimensions, or in fact, not even as
big as the atom as a whole, since the emission comes from the electron
that changes orbit. Of course, electrons have no definite size - their
mass is so low that they are more like fuzzy blobs than tiny balls.
Photons, having no mass, are really quite big (;-).

Alex: I used a little 6 dollar kit from Ramsey Electronics. I think there is some information on what we did and how we did it on my web site:

http://www.erols.com/wmeara

There were also some QST articles on ways you could modify a Radio Shack Vox circuit.

We had a lot of fun interfacing Internet Phone with my VHF ham gear (at the time I was in a location where this was legal). I used to get calls from around the world on my 2 meter HT!

This was in 1995. At the time there was a lot of ham activity on Internet Phone, but when I checked in a while back, I couldn't find any hams. Where are the hams who are using I-phone like systems hanging out? Pow-wow? Other software?

Photons have no rest mass, but e=mc^2 means that they all have some
mass, and some of the shorter X-rays and gamma rays outweigh an
electron. Such photons are - of course - very small.

Please read the Relativity FAQ.

The correct expression (viz the PDG review on relativistic kinematics)
is that
E = sqrt{ (mc^2)^2 + (pc)^2 }

For a photon, with a mass m less than 2 x 10^{-16} eV/c^2, this
reduces to E = pc for all photons of interest, not E = mc^2.

You get E = mc^2 when p = 0.

Has anyone thied the "Clearspeech Speaker" by Am-Com of Lakeside, Montana? The QST Ad states that the speaker will filter 95% of of the background noise. I was just woundering if it is worth the $130 price.

So far, so good.

> but e=mc^2 means that they all have some mass,

No. The 'm' in E=mc^2 is the (rest) mass. That formula only applies
in the rest frame, as it's a special case of the more general formula
E^2 = p^2c^2 + m^2c^4 .

> and some of the shorter X-rays and gamma rays outweigh an
> electron.

They have more energy than an electron. They still have no mass.

> Such photons are - of course - very small.

I don't think that's a meaningful statement.

Ed, a simple way to make a power supply is to use a 723 integrated circuit. This is used by Astron and many other power supply companies. For application notes on this device, try web pages of National Semiconductor, Texas Instruments, Motorola, and the like. They publish schematic diagrams that you can use as is, in conjunction with a simple full wave rectifier and filter. You might have to send email to these companies and ask for data sheets and application notes, if the info isn't on the web page.

You can design it for a wide range of output ratings, depending on the transistors and transformer you use.

2345. L.O.S.A - List of Stamp Applications [000320]

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-21 00:00:00 UTC
From: cjX@hth.com
Message-ID: <38d7af15.67525782@news.sverige.net>
Source record: 62284
Cross-posted to: comp.robotics.misc,comp.home.automation,sci.electronics.misc,rec.radio.amateur.homebrew

Hi,

Below is the latest index of L.O.S.A and you can download the
complete L.O.S.A from the following places...

WWW:

http://www.hth.com/losa/

FTP:

ftp://ftp.parallaxinc.com/pub/text/losa.txt

1.0 What is L.O.S.A all about?

This list was started back in -95 when I heard about (more or less)
uniqe problems that was solved by using a BASIC Stamp. Especially Guy
Gustavson's story (see #001) about how he saved his beloved cat Kesha
gave me the inspiration to start writing L.O.S.A. I hope Kesha still
is alive and having a great life. Now 5 years later there are 180+
applications described and I hope you will enjoy reading all (or
parts) of them.

The main purpose of this list is to get an idea of what other people
are using their BASIC Stamps for and maybe get some inspiration or
hints for your own projects. Some of the projects described in the
list also have links to source code and schematics for download.

1.1 How can I contribute to this list ?

If you have done something (big or small) with the BASIC Stamp that
you are willing to tell others please use the form given below and
write a short description, nothing fancy is needed just a simple
explanation. If you have source code to share that's even better but
it's not necessary.

Visit the following Web site and fill in the contribution form...

http://www.hth.com/losa/

1.2 Why are some links dud's ?

Since people changes their e-mail and web addresses some links may be
dud's. If you previously contributed with one (or more) of the
applications please take a quick look and check your e-mail address

and/or web-links. I'm only able to keep the list updated if I'm
informed about changes, thanks in advance.

1.3 List of contributions

So how do they manage to have momentum? Or is a light sail another
fallacy? And they interact with gravitational fields, which presumeably
implies that they have a gravitational mass, and can bend space on their
own account.

> > Such photons are - of course - very small.
>

Photons have wavelength, which has the dimension of length. Precisely
what sort of meaning were you looking for?

Hello all:

My Heathkit HW-101 transceiver is having some trouble on the 28.000 to 28.500 band. I suspect the crystal or the crystal holder. The received band is intermittent. I once took the crystal out and looked at the holder. It seems as if the last owner "wallowed out" the insert where the crystal leg goes. I tried to fill in the gap by using AL foil on the leg and inserting it into the holder. It worked for a short time then nothing again.

Any suggestions?

Curtis Scholl
cscholl@izzy.net.

Bill, E = mc^2 can't be the whole justification. E = hv comes in as
well. That gives m = hv/c^2, which is why light is bent by gravity (but
not very much!). (h is Planck's constant and 'v' (which should be the
Greek 'nu') is the frequency of the photon radiation.

Still, thanks for posting, because it has given me the clue to refine
another post in this thread.

> pinning down the shape) as it goes by (by however impractical
> an experiment)?

Well, I have not been able to pursue this as far as I would like. The
basic idea, which I believe is orthodox physics, is that the rate of
fall of quantum-mechanical probability with distance from the 'most
probable' location is inversely proportional to the mass of the object.

So, electrons are not only much bigger than, say, protons, but are quite
'fuzzy' at the edges, since the rate of fall is very low. However,
extending that to the photon appears to require that the rate of fall is
zero, and thus the photon is infinitely large (and/or has no 'maximum
probability point'). Presumably then, relativistic contraction means
that it has no dimensions along the line of flight (in vacuo), so it is
just a doubly-infinite straight line perpendicular to its path. No
wonder they get entangled so easily. (;-)

However, photons carry energy, and, as Einstein showed, that energy is
equivalent to mass. The energy is E = hv (h is Planck's constant and v
is the frequency), and E is also mc^2, so that m = hv/c^2. Considering
that h is very small and c is very big, only photons whose v is very
high indeed (X-rays) have masses even comparable with that of an
electron, so most of them, especially 50 or 60 Hz photons (!), are
enormous.

Actually, I'm not even talking about the regen circuit. Yes, it
sends out noise, but when the old talkie was keyed up, a CB about
20 feet away hits S9 on *any* channel. THAT's a bad signal!
Obviously your mileage may vary.

Momentum, in general, is not related to mass.

>Or is a light sail another fallacy?

No, not at all.

>And they interact with gravitational fields, which presumeably
>implies that they have a gravitational mass,

Again, no. Gravity shapes space (space-time, more exactly),
everything in this space time acts accordingly. No mass required.

>and can bend space on their own account.

They've enery.

> Any suggestions?

Most likely the crystal holder was 'wallowed out' from constant changing
with another crystal---TO GET ON THE CB BAND BREAKER BREAKER BROKE C'MON
SKIPLAND... best just to replace the holder. Those HC-6U holders are
fairly easy to find. Maybe, with the use of a small screwdrive you can
squeeze the prongs together to get a tighter grip on the pins. Maybe
you can desolder one end of the pin and straighten it in order to push
it through the holder to squeeze it together with pliers---then replace.

Sincerely

Nope. The momentum of a massive particle, in Newtonian mechanics, is
mass times velocity. Momentum in general can be many different
things.

It is important to read equations properly. Suppose I write the
Newtonian expression for kinetic energy, i.e.

E = (m/2)*v^2

Now, this doesn't read "Energy is half mass times velocity squared"
What is says is "The energy associated with the motion of a body is
half mass times velocity squared". An important distinction. Do you
see it?

Take out the 2 screws that hold the vox switch in place. The bulb is
easy to replace then.

2360. dummy load - power dissipation question

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-22 00:00:00 UTC
From: Nick Caruso <nick.caruso@software.com>
Message-ID: <38D94A26.BCC165D9@software.com>
Source record: 62099

I've got a couple of 100 ohm 1% noninductive resistors which claim to be rated at 20 W each. I was thinking of paralleling them and building a dummy load.

My question: how much power can such a thing handle, continuously? I imagine it could tolerate 40 W intermittently, but how much should I derate it for continuous use? 50%? 70%?

I'm considering doing the "Cantenna" thing and putting the resistors in oil inside a paint can. I have several questions on this topic! :-)

1) how much will this increase the continuous rating of the load?

2) where can I get transformer oil??? Will 10W40 do?

3) shouldn't the resistors really be mounted at the bottom of the can, so convection in
the oil can help distribute the heat? Would this make enough difference to make the
mechanical problems of mounting the RF connector to the side and sealing it worth
the trouble?

and finally,

4) do I immerse the resistors right in the oil, or is some sort of covering needed?

thanks and best regards,
nick

Hello--

If the PC board include bottom-side traces or through-hole components,
you might try using small plastic beads with center holes that'll pass the
board's mounting hardware. A visit to any store that sells arts'n'crafts
supplies should have suitably-sized beads.

You can also use double-sided foam sticky tape to attach the board to the
tin, or blobs of hot-melt glue.

The reason I think the straight line idea has merit is that if the
bending is due to some idea that the energy/mass equivalence is at work, then
high energy/mass photons should curve less than low energy/mass photons. And I
haven't seen any evidence of that being the case.

2363. Re: Filter for 169.5-170MHz

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-22 00:00:00 UTC
From: Tom Bruhns <tom_bruhns@agilent.com>
Message-ID: <38D95FEB.32A0B528@agilent.com>
Source record: 62102
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

I did some playing with "real" numbers on this. If anyone would like the MathCad worksheet I used, just email me. In summary, I assumed a piece of coax 0.9 times a quarter wave long on 160MHz. I ran it for both RG-8-type and RG-11-type coax, each 0.285 inches dielectric diameter, each 0.66 velocity factor (solid polyethylene dielectric). So, that's an 0.278 meter length of line. That tunes with a small capacitance on the open end: about 2.1pF for 75 ohm line and 3.15pF for 50 ohm line. You need to put a very low inductance across where the stub attaches to the thru line to tune it to minimum reactance at the pass frequency (I assumed 146MHz). It's about 8 nanohenries at 75 ohms and 5.5 at 50. You could get the inductance from a short shorted stub. (Note: then it looks like the line is tapped up on a coaxial resonator...this is pretty general: make a resonator, shorted at one end and open at the other. Tap the thru-line up on it; adjust the tap point to adjust the notch frequency.) At the null frequency, the RG-11 trap looks like about 0.155 ohms resistive across the thru line, and the RG-8 looks like about 0.092 ohms. That hints at the depth of the notch: 50 dB or so. At the pass frequency, assuming the tuning coil has an unloaded Q of 100, the RG-11 trap plus inductor look like about 273 ohms, and the RG-8 system looks like about 196 ohms. I'd personally opt for the lower disturbance of the RG-11 trap...or use larger trap coax to get to lower pass-frequency loss.

With luck I didn't make too many math mistakes, and I hope this will be useful and interesting to someone out there!

Cheers,
Tom

You should investigate what the "noninductive" label actually means.
In some cases at least, such resistors are actually resistance wire
wound as a coil on an insulating rod. The noninductive versions
use a bifilar winding, so half the turns are carrying current in
one direction and the other half carry it in the other direction.
In theory, the magnetic fields cancel and you get a noninductive
resistor. But there's probably some residual inductance - not enough
to be troublesome at audio frequencies, but possibly a problem for RF.

Although the photon has no rest mass, it does have momentum p=h/lambda.
If it
collides with something, it can transfer this momentum. For macroscopic
objects, the
force is small, but for something small, like an atom, huge forces can
be involved. This has given birth to a large area of physics that
studies the cooling and trapping of neutral atoms with light, and the
1997 Nobel prize has been awarded to some prominent researchers in the
field. So far the ad.

My good buddy Albert says that light *isn't* affected by gravity. He says that light always travels in a straight line. He says that it's space its self that gets bent by gravity. The light just takes the shortest path which is a straight line which only "looks" bent.

If light were affected by gravity, it would make sense to me that red light with less energy would be affected less than blue light with more energy. Have you ever heard that white light gets split up into a rainbow as it passes by something like the sun?

There are things called "gravity lenses", but AFAIK they are achromatic lenses.

A search of the internet using "gravity lens" turned up some information. The sad thing was that fully two thirds of the sites found were concerned with crack-pot new-age bullshit.

One decent looking page was:
http://faraday.physics.utoronto.ca/PHY100F/relgen.htm

Sorry, I forgot about the preposterously broad cross-post. This
is such an FAQ that I typed that automatically.

We always use 'p' to denote momentum, and in this case it is
the familiar 3-vector momentum, albeit the relativistic one.

Not so. If you use m = E/c^2 as a gravitational mass, you also do
not explain effects observed in nature. General Relativity is not
so simple, as is explained in the Relativity FAQ.

Does anyone know of a low-noise, small-signal FET op. amp. type number that will work as a differential RF amp. up to 30 MHz? The 97 arrl handbook suggests a Harris
HFA-1102, but I am told that Harris is out-of-business?

Also, can slightly mis-matched components be tolerated or compensated for afterwards, if one were to homebrew an op. amp. out of discrete components?

Tnx, Ed W. K3FDY

Yes. It's called "Compton scattering" and is usually discussed in physics
textbooks in connection with scattering photons off of electrons.

>probable' location is inversely proportional to the mass of the object.
>
It's inversely proportional to the uncertainty in its momentum.

>So, electrons are not only much bigger than, say, protons, but are quite

Except that scattering puts a limit on their rms charge radius at
< 10^17 m. You may equate their "size" the probability of finding
them in some area determined by the circumstances, like an
atomic transition, but then you have the definition of a cross
section. The relation of the cross sectional area to the mass
is just the phase space factor in fermi's golden rule.

>zero, and thus the photon is infinitely large (and/or has no 'maximum
>probability point'). Presumably then, relativistic contraction means
>that it has no dimensions along the line of flight (in vacuo), so it is

Suppose an observer at the origin has a source that emits a photon
at time t=0 within the limits of the uncertainty principle. From
that observers perspective, the photon be anywhere, since he
can no longer reach a distance the photon cannot have yet reached.

>just a doubly-infinite straight line perpendicular to its path. No

However, any path is perpendicular to its path, including its
own. the momentum q, is perpendicular to itself, q^2 = 0.

>However, photons carry energy, and, as Einstein showed, that energy is
>equivalent to mass. The energy is E = hv (h is Planck's constant and v

What he didn't say is that it means you can always find an independent
object corresponding to that mass. When a 13.2 eV photon is absorbed
by a hydorgen atom in its g.s., the resulting electron and proton
have a larger mass than the hydrogen atom. That doesn't mean you
can find that 13.2 eV mass in a representation free way (i.e. its own
little chunk of stuff). I think it works better to interpret both
masses and energies as momenta and c as a scaling factor.

>is the frequency), and E is also mc^2, so that m = hv/c^2. Considering

In E = mc^2, m is understood to be a rest mass which requires an inertial
frame (p=0) to define. Without defining an inertial frame, you're stuck
with:

Etot = Ekinetic + Erest

E^2 = p^2 + m^2 (I set c = 1 so E=mc^2 reduces to E = m)

but E^2 isn't invariant, E^2 - p^2 is.

For a particle with a rest mass, when p = 0, E = m, or with the
c^2, E = mc^2. If m = 0, then E^2 - p^2 = 0, which is fine
so long as E = p (or with the c back in place E = pc).

Or in other words, For a given E, you cant find m unless you
know p. Using the four-momentum that is just defined by the
invariant E^2 - p^2 to be q = (E, p) = (p0, p1, p2, p3).
you get the einstein condition for a free photon:

q^2 = p0^2 - px^2 -py^2 -pz^2 = E^2 - p\cdot p = 0.

According to relativity, the norm of the photon four-momentum is
identically 0.

>that h is very small and c is very big, only photons whose v is very
>high indeed (X-rays) have masses even comparable with that of an
>electron, so most of them, especially 50 or 60 Hz photons (!), are
>enormous.

Taking your argument literally, it means more; they extend over all of
space, since you have a monochromatic photon or in other words,
your source has been on infinitely long and the photon is produced by
an interaction with a lifetime of infinity (or a probability of zero)
and in still other words is not observable. So, you need a spread in
frequencies constructed as a packet that is sharply peaked at the
frequency of interest. If the uncertainty in energy is \delta E,
the process that produced it can be determined in time with an accuracy
constrained by \Delta E \Delta t =~ \hbar. That means \Delta t
that is the uncertainty in emission time is \hbar/\Delta E.
If it's uncertain by \Delta t when the photon was emitted, it's
uncertain by a distance c \delta t, where it is. If that interval
represents the bulk of the probability (in a gaussian it's the 1/e
point so it does), then that's how "big" you'll call the photon.
I leave it to you to find reasonable limits on \delta E for
a photon of energy E and what happens for "bigger photons"
(\Delta t large) and "smaller photons" (\Delta t small) before
it isn't clear what E should be or how long you should wait before
seeing one from the source.

OK. Suppose you drop a mass from a height h and suppose you convert its
mass and the kinetic energy it gains by falling into a photon with an
energy equal to mc^2 + the kinetic energy. (you can argue for a fractional
anount, too). Unless the photon loses the kinetic energy gained by the
falling mass in order to climb in the field (is red shifted), you
can create perpetual motion, since you have more energy at the point
you dropped the mass than the mass had to begin with. Converting
the photon back into a mass gives you a bigger mass than you originally
dropped.

Two thoughts come to mind.
1 the crystal may be intermittant. They sometimes make poor contact internally. This can occur if the hermetic seal is damaged, and the crystal contacts have oxidised inside.

2 the oscillator coil needs tweaked. if you tune to peak oscillator output, the circuit becomes hard to start, and sometimes will oscillate only intermittantly, dependant on temperature and voltage changes.

Lyle - I agree with you up to a point. It's absolutely right that max
power is extracted with a conjugate match and the process produces
a tuned circuit. But if the source impedance is a resistance in series
with a reactance, and you are only allowed to use a load resistance
without any reactance, then maximum power (at a lower level) occurs
when the load resistance is equal to the modulus of the source
impedance. I think that's what he is trying to say. It's a modulus match
and can be used when wideband performance is required.

I have found that the L/C Meter IIB from AADE (Almost All Digital
Electronics) is a very handy device. For $99 (kit), %129 (wired) it is
reasonably precise and useful for inductances below 100 nhy (most
other inexpensive inductance meters are worthless below 1 uhy.

It's available at: http://www.mtechnologies.com/aade.htm#lcm

The circuit is very clever. It contains an LM311 comparator set up up
as an LC oscillator. The internal capacitance is trimmed to 0.5% by
the manufacturer. It is self calibrating. Knowing the capacitance the
internal inductance is calculated. The change in frequency with an
inductor in series or a capacitor in parallel is used to calculate the
inductance or capacitance. All of this is done on an internal
microprocessor. There are several variations on how the data is
displayed. Very neat. And the packaging is reasonable for such an
inexpensive instrument. I own 3.

Recently I purchased an HP4192A for $5,000. Yesterday I did a
comparison test on a large 350 uhy coil. It measured within 1% of the
same value on both instruments.

I am taking orders for 4cx400/gs36b Svetlana nos Russian Military tubes.
The price is $85.00 plus shipping per tube. These tubes are in great
shape and have never been used.
I also have in stock several matched pairs
of 4cx800a/gu74b Svetlana nos tubes. These are the tubes for the Alpha
91b/99 QRO-2500, the Acom-2000, and the Emtron amp from Australia. The
price on these matched pairs is $200.00 plus shipping. This is a great
buy on these nos unused tubes. A single 4cx800a from most places will
cost you $175.00 to $190.00, but these are matched pairs for about the
same price as a single tube. These tubes carry a 90 day warranty from
the Russian distributor.
Thanks for your time.

When my inverted-L is transmitting low power on 160m, and my
experimental 6 feet diameter 160m magloop is tuned up in the same
backyard, it collects enough power to burn holes in fingers. Now
that's REAL energy sucking. Easily numerically predictable by ancient
arithmetic. But doesn't make such exciting conversation !

I think you understood just fine, Jan-Martin. As J-M says, you should add some parallel inductance where the stub attaches, to cancel the stub's capacitive reactance at 144MHz. It's not the stub's Q, so much, as the reactance. If you use an "open" quarter wave stub, you should do something to extend the shield over the open end of the center conductor. You can also put a small variable capacitor across the open end to make it tuneable (maybe inside a little shield box); shorten the stub a little if you're going to do that. Use low loss line to get the greatest attenuation.

Since the stub will reflect nearly a short where it attaches to the feedline, another quarter wave back toward the antenna from there, you'll be looking into nearly an "open." If you put a second copy of the stub at that point (complete with paralleled inductor), it will be significantly more effective, because the signal will divide between the near-short of the stub and the near-open of the continuing line. You can also tune the notches to slightly different frequencies to get a broader attenuation band.

Cheers,
Tom

Ed...what 'zactly do you want to accomplish? If you want to implement a differential amplifier, op amps can work fine at lower frequencies, but you might want to think about just using a simple discrete amplifier, or use a balanced video amplifier IC. -- If you really want to stick with op amps, you might have a look on the Analog Devices and Burr-Brown web sites (and perhaps others such as Linear Technology, Maxim, and maybe National). The jfet-input B-B OPA655, for example, will give you low distortion and about 6nV/rtHz noise. Its GBW product, at 240MHz, should give you enough gain to be useful to 30MHz, if you don't ask for a lot of closed-loop gain. But they are pricey. Balance in an op amp circuit should be determined mainly by circuit topology and layout symmetry. To turn an op amp into a closed-loop differential amp, you'll have to put some resistors around it, and you'll ruin the noise figure unless you use something like the three op amp instrumentation amplifier configuration. And that will get you up in the $50 range just for a set of OPA655's! (Is there a reason you really need jfet inputs?)

Cheers,
Tom

I used double-sided foam tape once in a demo box (about 50 copies of it)
we made to show off one of our products. It held a small, light-weight
board. We found that they'd come loose after a while. I ended up
adding a screw to ones that came back with the board flopping around
inside. "YMMV" as they say. Another option in an Altoids tin is to
enclose the board in foam cut to the volume of the box and just close
the lid. Quick, simple shock mounting. Can handle a battery that way,
too.

Cheers,
Tom

In a word, "velcro".

In more than one word, you can get self adhesive velcro strips
at any hardware store. They are easy to cut with a pair of
scissors. Place a full size pad on the bottom of the box
and stick strips to the edges of the boards. The boards can
be easily removed without any tools and they will never
shake loose.

Martin

Thanks. Clearly something has happened to 'momentum' since I learned
about it long years ago, that I haven't seen explained anywhere. I
learned that momentum (for things like billiard balls) was mass times
velocity. That would make '(pc)^2' dimensionally inconsistent with mc^2,
as well as being zero for a photon!

I see from another post that the momentum of a photon is h/lambda, which
is hv/c (v = frequency). That is consistent with E = hv, I suppose,
because (pc)^2 = (hv)^2. I don't really see that introducing momentum is
helpful, unless maybe to explain why the Einstein and Planck energies
don't add arithmetically. Not that it matters anyway, of course, if the
Einstein energy is zero.

I really think that is semantics, or maybe philosophy. Every test we
could apply shows that the path is not straight, so what is the point of
maintaining that is 'is' in some abstract way. I don't think he did his
cause any good with such 'explanations'. Of course, in those days it was
not unusual to mix philosophical statements with scientific ones, and
the practice is not entirely dead even today.

2402. Re: dummy load - power dissipation question

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-23 00:00:00 UTC
From: Matt Erickson <kk5dr@hotmail.com>
Message-ID: <38D9716E.24E09D76@hotmail.com>
Source record: 62107

How long do you intend to transmit into the dummy load? A week?
Two 20W resistors in parallel dissipate 40W continuous.
Putting them into oil, will increase the heat dissipation about double or more.
Oil is not critical, I use good ole ATF, works just fine, and can handle very high heat levels.

2403. Re: small-sig. diff. amp.

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-23 00:00:00 UTC
From: K3FDY <edek@mail.gcnet.net>
Message-ID: <cyfC4.478$DY4.54810@typhoon1.gnilink.net>
Source record: 62108

Tom:
The small HF loops I make have a closely coupled pickup winding which serves as the output. The restriction on sig. pickup method is a matter of packaging and convenience, as opposed to maybe having the pickup winding located externally. The tight coupling works fine as long as the terminating Z into a receiver is relatively high, meaning a few K to 100 K. The higher the better, I have discovered. Working into the usual moderate to hi-z input of battery portables the coupling method works very good barefoot, but coupled into a 50 ohm, or even 500 ohm input, the Q and subsequent gain diminishes considerably. To overcome this, I have used a an unbalanced, two-stage FET/Bipolar amp.. This resolved the impedance match, but on line-operated equipment, I notice that noise rejection is not comparable with a battery portable at the very same location, plus with the hi z input (100 K), I notice a greater tendency to pickup spruious signals on line operated equipment (with my Kenwood 530S at least)? Assuming that the loop operates best when things are symmetrical, and in my case, with high Z output, it seemed logical to use then a differential amp. which offers both characteristics. Also, since the output cabling I use is a 32 inch, #30 guage, teflon twisted pair, the common-mode rejection feature of diff. amps. will work to negate stray pickup at this point also, I presume?

Retired, and as a hobby, I started to tail-gate similar loops at hamfests a couple years ago, explicitly for battery portables, but as they got somewhat popular, certain users would invariably try to use them on 50 ohms only to be disappointed, so now, it seems that I need to devise some better coupling method? Ferrite balun experiments didn't work across the whole spectra, apparently for wide impedance swings and extremely high Z preferred? As I have more time than test equipment, I merely do things by experiment. It also has been a while since I have been a bench technician.

Thanks for the input.
Ed W.

Not at all. The shortest distance between two points on the
surface of the earth is a Great Circle. Exactly the same
sort of thing. There is a good introduction to this in the
Relativity FAQ.

>Every test we
>could apply shows that the path is not straight, so what is the point of

Because the experimental evidence suggests it is not abstract,
just as the evidence suggests that it is not an abstract idea that
the earth's surface is curved.

2405. Re: Clearspeech Speaker

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-23 00:00:00 UTC
From: K3FDY <edek@mail.gcnet.net>
Message-ID: <GzgC4.481$5X.51786@typhoon2.gnilink.net>
Source record: 62110

Bob:
As a cheap experiment (originally for CW), I took a 1-3/4 inch, 8 ohm,1 watt surplus speaker from All Electronics and mounted it at the center rib of a 1-1/2 inch sked 40 PVC coupling. Then I attached corresponding end caps, joined with stubs of 1-1/2 inch pipe. The overall length is about 4 inches. The speaker leads are brought out through the side of the coupler and plugged with poster putty. Prior to assembly, I stuffed the unit with fiber-glass insulation, using a circular piece of window screen to protect the speaker cone. On the forward, cone side, I drilled a tiny, 1/8 inch hole for the sound to exit. Hooked to a couple watts of audio, you will be surprised at how much sound will eminate through the small hole at the resonant frequency at about 600 Hz. As a single-pole filter, the response is not real sharp, but as for limiting noise and especially lightning crashes, it works quite well. Lightning crashes make but a smooth, puttering sound, not objectional at all. Additionally, I am playing around with internal baffling as with a folded horn, and more exit holes around the perimeter of the cap., which looks (sounds) promising as I am trying it on SSB with reasonable results. It is important to use at least a 1 watt speaker, as the system is highly damped and lossy, but the damping is a good feature. In general, keeping the speaker cone travel limited with a tight enclosure allows the speaker to be used considerably above its stated rating as voice coils especially overheat when they lose inductive reactance by exiting too far beyond their pole piece. So far, I haven't popped this speaker with some hard use. When the system is at resonance, one can feel a considerably amount of air being pumped through the small hole. This is one way to tell when it is at resonance. I have no idea whether All Electronics still has this speaker. The orig. cat. no. was SK-175, @ $1.25, slightly cheaper than the alternative you mention? Good luck. Ed W. K3FDY.

I have a possible cause. If the crystal is in a soldered small can what
often happens is solder flux from the solder that seals the crystal holder
can over time permeate to the crystal blank and make the activity of the
crystal poor also lowering the frequency somewhat because of the added mass.
Sometimes moving the crystal around or even changing the tweak capacitor
makes it OK for a while. I had the exact same problem you described with an
old FT301 one time. What I did which worked for me is to unsolder the base
of the holder and clean the crystal with solvent. After drying thoroughly I
resoldered the can back on and all was OK.

Good luck
Jim Ford, N6JF

2407. Re: dummy load - power dissipation question

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-23 00:00:00 UTC
From: W5LZ <w5lz@oio.net>
Message-ID: <38D9FC67.B2AF888@oio.net>
Source record: 62112

Nick,
Power ratings are additive when resisters are in parallel. If you
wire 5 20 watt resistors in parallel, you have a total power disipation
of 100 watts. If possible, you wanna build in about a 50% safety
factor,
so a total of 150 watts for a 100 watt dummy load.
If your thinking of the 'cantenna' type dummy load, do NOT use motor
oil! Motor is flammable. Use mineral oil instead. In the same vain,
do NOT use a glass container! The reason for that isn't too hard to
figure out. Also, besure to put a presure relief hole in the lid of
the can. And yes, submerge the resistors in the oil.
'Doc

I'll bet they are not non-inductive at RF!
I've seen metal body wire wound resistors used in magnetic deflection circuits
marked non-inductive! (but they are NOT good at RF.)
You want a stick of resistance material or thick film on a ceramic form.

Source record: 62115

From a purely technical standpoint, the loss in a cable is directly proportional to it's length. Therefore, the shortest length (in a matched system) provides the lowest loss. However, the system itself may be able to withstand many times the loss you get from a longer cable and you would never notice it in reception.

I've tried it and IMHO it works quite well. I would describe the S/N improvement as 6 to 10 dB (subjectively) which is not quite 95% but getting there. It greatly reduces listening fatigue by getting rid of white noise, and it doesn't cause much distortion of the original signal (voice or CW).

One important limitation: it will *not* pull an uncopyable signal out of the noise. It will just make a marginal signal easier to listen to. So it is probably more useful for the ragchewer than the DX or contester.

It also works great for nulling heterodynes automatically. It is *much* better than the notch filter on my FT1000 for this.

I have not used any competitive DSP boxes, but others who have say this is the best.

Hello all,
I found this in the Washington Post yesterday.

This seems to fit in well with the rants and raves of the recent thread
and violating the regular laws of physics in the least time.

Does anyone know anything else about this?
Regarde' Scott

A. S. Chesnick
Engineer
In Vivo Center for Nuclear Magnetic Resonance Imaging
National Institutes of Health
Bethesda, Md. 20892

MINNEAPOLIS, March 21ï¿½Two California physicists
announced today that they had created a new class of
materials, never before seen in nature, with highly unusual
properties that may have applications in fields such as wireless
communication.

The materials, described as "left-handed," reverse the normal
way that microwave energy--including such standard natural
phenomena as the Doppler Effect--behaves, the researchers
said.

"This is Alice in Wonderland. The effects get curiouser and
curiouser as we go through them," said Sheldon Schultz, who
with his colleague David R. Smith, both of the University of
California at San Diego, spoke to reporters here at a national
meeting of the American Physical Society.

The researchers displayed a sample of the new
"meta-material," and it appeared to be something that any
tinkerer might hammer together in a basement. The scientists
mounted studs of copper wire on a metal plate and interlaced
them with thin strips of copper rings, everything held snug
with strips of Styrofoam. The sample could easily be held in
one hand. The innovation is not in the raw materials, but in
their arrangement. When microwaves are beamed through the
material they become focused rather than diverging, as they
normally would, the researchers said.

It is the combination of the specially designed copper rings
arranged against the copper wires that gives the material the
property of reversing the normal response to energy, the

researchers said.

"If these effects turn out to be possible at optical frequencies, this material would have the crazy property that a flashlight shining on a slab can focus the light at a point on the other side. There's no way you can do that with just a sheet of ordinary material," Schultz said.

Three physicists with no connection to the research who attended the presentation agreed that it was an exciting development. The materials obey all the normal laws of physics, they said.

"It's not backwards in time. It's not making you younger. It's not science fiction. It's not spooky," Schultz said. "It opens up a class of materials that just have not been available."

Their paper describing the advance--"A Composite Medium with Simultaneously Negative Permeability and Permittivity"--will be published soon in the journal Physical Review Letters.

The paper written by the scientists was initially rejected without review by Physical Review Letters. The scientists blamed their inability to explain the significance of the work. Then Smith, combing through scientific papers on "negative permeability," came across an obscure paper from 1968 written by a Russian theorist, V.G. Veselago. Veselago predicted that a material with electric and magnetic response to electromagnetic radiation that is the opposite to the norm, if such a thing were ever found or invented, would reverse the manner in which the energy traveled through it. "We didn't understand there was anything special about it until I found that paper," Smith said.

From Veselago, Smith picked up the term "left-handed." Smith and Schultz and three colleagues at UCSD then elaborated on their description of their work in the original paper and this time got it reviewed and approved by three anonymous experts.

Smith said he found out only early this week that Veselago is still alive. "He said in some sense he had written it off as a joke, because he didn't think it would ever be realized," Smith said.

Schultz, 67, said it was the most important development in his 39-year career. Smith, 35, said his team filed for a patent only this past Friday. The research is clearly competitive: The scientists acknowledged a debt to a British physicist, John Pendry of Imperial College, London, who in 1996 had described a way to use ordinary copper wires to create a material with certain left-handed qualities. The California

scientists said they believed Pendry is also seeking patent rights for materials he has produced.

The scientists were quick to acknowledge that the research is in the early stages and that they don't yet know what may come of the discovery. Since they have shown that the materials have a dramatic effect on microwave propagation, they assume it might be used in the wireless communication industry--for example, in the construction of antennas.

"Don't ask me to predict the next whiz-bang left-handed materials company," Schultz said.

Art

2422. Unknown ferrite cores for wide band transformers

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-23 00:00:00 UTC
From: LA8AK@online.no
Message-ID: <38da6034.261748032@news.online.no>
Source record: 62127

Many unknown cores are in the junkbox, here is a way to decide which is useful, at least for 80m. Similar procedure can be tried for other cores, the FB43-2401 might not be too 'unknown' but describes how to sort out a problem

Quote LA7MI: Reactance for the lowest frequency band in use shal be 4 times higher than the actual impedance. For a 50 ohm winding the reactance should be 200 ohm, ie. 9-10uH on 80m. With some cores like Amidon FB43-2401 (u=800-2000) one must use higher reactance, might be better to use a core with lower permitivity. But the cores were bought at low price at a flea marked in USA, so I would make some tests to see how to use them. One may test by winding one turn on a toroid core and connect to the signal generator with - say 1V RF output voltage. Let the generator stay connected for 15-20 minutes and check if the core has been warm. If it just feel somewhat warm this is within the acceptable limit of use. Output voltage for a solid state power amplifier with 12V supply is 8-9V. With Amidon FB43-2401 it is better to stack 3 cores in parallell with 3 turns instead for using one core with 9 turns winding.

A power generator is used, if you wish to see the circuit please send me an email.
Figure 32-1 shows LA7MI power signal generator with RF power output 0-1.5W @3.7MHz

Well, a guy was selling them at the MIT Flea as "non-inductive -- suitable for making dummy loads". I dunno what's inside, but they're encased in heavy metal bodies with heat sinks on them.

Now, I'm a trusting person, but I *was* planning on sweeping the load with an MFJ-249 antenna analyzer to see what the SWR looked like before I actually transmit into the thing... Maybe I'll do a quick and dirty test by soldering one of them to an SO-239 and sweeping that.

Would this be a sufficient check?

2424. Antennas & Transmission Lines.

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-23 00:00:00 UTC
From: Reg Edwards <G4fgq.Regp@btinternet.com>
Message-ID: <8bds1n$q5l$1@uranium.btinternet.com>
Source record: 62129

The following is an extract from a reply in another newsgroup. It may be of interest here.

Antenna conductors behave as transmission lines. Example - a horizontal end fed wire is a single-wire line above a ground plane. A horozontal dipole is two single-wire lines. A vertical is also a single conductor line above a ground plane.

All transmission lines have a characteristic impedance Zo = Ro + jXo which depends on dimensions such as length, diameter and height above ground. All lines also have attenuation (dB per metre) and propagation velocity (phase shift, radians per metre). With antennas the radiation resistance is a principal cause of attenuation and can be lumped together with conductor resistance.

The input (feedpoint) impedance, Rin + jXin, of any transmission line can be calculated from frequency, its length and terminating impedance. For example the terminating impedance of a vertical antenna or a random long wire is an open circuit. The terminating impedance of a full-wave loop is a short circuit.

The process can be reversed. The terminating impedance, it may be an antenna, can be computed from measured input impedance of the antenna's feedline. Useful if you are unable to take the impedance bridge up to the centre of your dipole. Use program ZL_ZIN.

Most of the programs available from my website involve input impedances of transmission lines for various terminations. For example, the first length of line of a loaded dipole is terminated with a loading coil followed by a second length of open-circuited line. A Beverage antenna is terminated in its own Zo. A magloop is terminated with its tuning capacitor. Amongst other things RJELINE3 solves the same problems as a Smith Chart, faster and more accurately.

For examples of practical use of calculations download programs from my website below. Each downloads in a few seconds. Not zipped up. Run imediately. User friendly.

Nemo pointed out on s.e.d how insulting this was to all of you. I apologize most humbly and sincerely. I was thinking of the time it will take to get the source in shape to post as I promised. Nail me if I do that again.

I would be honored if people took the time to look at this concept. I would love to take part in discussions on this approach. There is a good chance they can degerate into serious misunderstandings, especially when noise is the main topic. We need to guard against that possibility. There is a lot I do not know about this concept. I do not know what the limits are. I do not know what the dynamic range will be. It has many unknowns. This can lead to misunderstands. Please try to be patient and a bit tolerant. Maybe we will all gain something.

I would be especially interested in the results obtained by anyone who tries it. My lab equipment is limited, and right now the main focus is on the simulation software. You guys have a much broader range of interests and frequency range.

That should be sufficient for HF. I wouldn't trust it for VHF or
above since the lead inductance could become a factor.

What brand are the resistors? Are they sort of a golden brown
anodized aluminum case with leads with eye-holes on each end? Do
they have mounting brackets, one on each opposing end to screw them
down? (I'm trying to describe these as best as I can.)

I tried making a dummy load from these once before, and it worked
fairly well (but not perfectly) on the bottom end of the HF
spectrum, but it was pretty awful on the upper end, and was just
plain useless on VHF. I'm not sure if it was because they were
(non-inductively) wire wound, or if it was the metal case that was
causing excessive capacity.

But, give it a try and see what happens. If it doesn't work, well,
you can always make a foot warmer out of them for winter. :-)

As for construction techniques that you'd asked about earlier, remember that oil is messy. I'd recommend not drilling a hole in the side of the can due to concerns about leakage. One construction technique I've seen is to use a paint can, and attach the connector on the top, and suspend the resistors about half way down in the can. Of course, the tricky part is making sure that the leads leading from the connector to the resistors act as a proper transmission line. You can obtain formulas to determine conductor spacing and size to treat them as a parallel conductor transmission line (Don't forget to include the permittivity of the oil in the capacitance calculations.).

Of course, as long as the leads are less than about a tenth of a wavelength, you probably don't need to worry too much (e.g., the leads probably won't be a problem for HF, but they would be a concern for UHF).

I've seen some designs that have incorporated a sleeve around the resistors to improve the thermal siphoning and circulation of the oil. An added advantage might be that the sleeve would act as an RF shield to limit the RF field (and it might make the transmission line analysis of the wires to the resistor easier to calculate, especially if the sleeve was used as the outer conductor of a coaxial style transmission line).

As a previous poster has mentioned, be sure to think about a vent hole (It's no fun to have the can build up pressure and relieve it by splitting a seam.). You probably also want to leave a slight air gap between the top of the oil and the top of the can to act as a expansion buffer.

The selection of oil can be a bit tricky. Transformer oil is usually recommended, but you have to be a little careful about it. Obtaining small quantities is not real easy, although some people have said that they can bum some off of the local utility company. In any case, make sure that the oil you obtain is not contaminated with PCBs (carcinogenic). This shouldn't be too much of a concern now, but if you stumble across a quantity of old oil, just beware of it.

Note that almost all oils are flamable, including mineral oil (Mineral oil is just a petroleum oil, as opposed to a vegtable oil, both of which are flamable). I've heard some people use cooking oil, but I can't necessarily recommend that. One of the concerns is to make sure the oil does not oxidize or become rancid (You don't want to take the top off a year or two in the future and find either tar or a slimy smelly mess.). Thus, you may need to add an anti-fungal, anti-oxidization agent which has to be non-conductive.

One of the other things you may think of is including a RF voltage monitoring tap to give you an idea of the power. Or, for the really complex version, you could mount a couple of thermistors on the can and measure the temperature rise to find the power being dissipated.

Some of the other construction techniques I've seen involve paralleling a quantity of Carbon composition resistors. For example, paralleling 20 2-Watt 1K-Ohm Carbon composition resistors will result in a 50 Ohm, 40 Watt dummy load (Well, you have to be a little careful about the tolerance of the resistors to make sure the power balances out.). And, by immersing them in oil, and limiting the duty cycle, you can push it quite a bit higher than 40 Watts.

Good luck with it. It sounds like a fun project (But, I bet you never thought something as simple as a dummy load could be so complex.). :*)

Dave

P.S. Standard Disclaimer: I work for them, but I don't speak for them.

There is a similar report in the British 'New Scientist' No 2231 dated
22 March 2000.

I would hope to see a material in which the permeability and
permittivity are of opposite sign, because the speed of light in such a
material would be imaginary.

The speed of light is the reciprocal of the square root of the product of the permeability and permittivity. So if both are negative, the speed of light is real.

Well, I've got 8 Burroughs B-5870ST Nixie tubes, but they're in an
old HP freq. counter I'm kinda trying to ressurect (I'm a bit of a nut
when it comes to old, ancient test equipment, especially Nixie's).

I suppose I could be persuaded though. Let me know what they're worth
to you...

2436. FS: RF components (long) for builders

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-23 00:00:00 UTC
From: Brad Thompson <brad.thompson@valley.net>
Message-ID: <38DAE75E.ECA7D64B@valley.net>
Source record: 62141

Hello-- Revised -03/23/2000

I'm offering homebrew builders the following NOS (new old stock) RF components, including...
***
Hewlett-Packard MSA-0786 MMICs ($1.00 each, $5.00 for 6, $10.00 for 15, or $25.00 for 50 pieces); DC-2 GHz. These are taped and reeled and have leads configured for surface-mounted applications.

Specs are available at HP's web site (or with your order)...

http://www.hp.com/HP-COMP/index.html
***
1N5711 Schottky diodes, full-length leads, taped and reeled, $1.00 for 10
pieces
***
1N5821 Schottky rectifiers, full-length leads, bulk packed, $1.00 for 8 pieces
***
PIN diodes, no other specs available; full-length axial-leaded packages;

individually serialized in sealed-foil envelopes. $1.00 each.
***
JAN 1N748A Zener diodes: individually sealed in mil-spec foil packets for your protection<g> in 1983.
$1.00 for 6 pieces.
***
SD-201 Signetics DC-2 GHz DMOS single-gate FETs four-lead TO-72 can (like TO-18 w/shield lead). A conductive-rubber antistatic "O" ring encircles
all four leads. Specs (available on request and with purchase) include S parameter plots. $1.00 each, $3.00 for 6, $5.00 for 12 pieces.
***
TN-2219A National Semiconductor NPN general-purpose NPN transistor: 100 < hFE < 300 at Ic= 150 mA; BVcbo = 75 V min.; BVceo = 40 V min.; Icbo = 10 nA max. at Vcb= 60 V; Cob = 8 pf max.; Ft = 60 MHz min. at Ic = 20 mA. NF 4 dB (max.)

In TO-237 metal-tabbed plastic package (similar to TO-92); this package reduces thermal resistance from 125 C per watt for a TO-92 to 50 C per watt
for the TO-237. Good for building a "desert island" QRP rig around a single
device type!

$1.00 for 20 pieces; $5.00 for 120 pieces

***
Minicircuits T1-1T (1:1 turns ratio (center-tapped)) broadband RF transformers (80 KHz to 200
MHz); leads are formed for surface mounting but you can rebend for DIP insertion. Visit
www.minicircuits.com for full specs via their catalog.

$2.00 for 3 pieces
***
Minicircuits PSCQ-2-400 90-degree, 2-way power divider, 0.9 dB insertion

loss, 225-400 MHz; $1.00 each
***
Fair-Rite cores (both type 43 mix):

2643023002 (a long-cored toroid) $1.00 for 10 pieces
2843002402 (binocular (balun) core) $1.00 for 20 pieces
***
Coilcraft p/n 142-07J08 single-winding adjustable inductors.
330 nH min./ 378 nH nom. /427 nH max.; 307 nH with tuning slug removed. Q is 112 min. at 40 MHz; 7.5 turn winding on 10 mm molded form.

$1.00 for 5 pieces; $5.00 for 35 pieces.
***
Chip Inductors: Coilcraft 1008CS family-- 10 by 8 mils, ceramic construction. Full specs are available at www.coilcraft.com

Coilcraft 1008CS-270XMBC 27 nH +/- 20 percent
Coilcraft 1008CS-470XMBC 47 nH +/- 20 percent

Coilcraft 1008CS-680XKBC; 68 nanohenry, +/- 10 percent, Q(min)=65 @ 350 MHz, self-resonant frequency of 1300 MHz minimum, Rdc = 0.2 ohms max., 1 ampere DC max.

Coilcraft 1008CS-332XKBC 3300 nH +/- 10 percent

$1.00 for 8 pieces of one value or any mixture of values

***
RF power xfmr.: consists of two 1.125-inch long by 0.570 inch OD ferrite sleeves with tubing primaries. Two small circuit boards short one end of the tubes, and the other two are not connected. A section of Teflon (tm)-insulated wire passes through both tubes' centers twice, making a 1:2 turns ratio (1:4 impedance) stepup transformer (you can easily remove this winding and replace it with more turns of smaller gauge) At a (nonguaranteed) guess, the assembly might handle 100 watts of RF. The cores are type 43 ferrite.

Price: $1.50 each (scanned image available on request)

***
Pulse Engineering PE-53190 toroidal inductor for switched-mode power

supplies.
Inductance = 12.2 microhenries at zero DC; 8.7 microhenries at 2.5 A DC.

Price: $1.00 for 6
***
SAW-stabilized oscillators; intended for ECL circuits, but also
reportedly usable as LOs. All are packaged in metal DIP cans.
$4.00 each, or three assorted for $10.00

Frequencies available are:
222.222 MHz (RF Monolithics HC1279; proprietary p/n marking)
350.000 MHZ (RF Monolithics HC1301)
366.667 MHz
400.000 MHz ($2.00 ea. but not NOS; removed from PC boards)
733.333 MHz
***
Teflon- and diallyl-pthalate insulated single-point turret lugs at
$12.00 per 100 (many styles available-- e-mail a request for
information and a jpg image showing various types).
***
Feedthrough capacitors: Spectrum Control 100 pf nominal (threaded
bushing mount, hardware included). Attenuation is specified as
-10 dB at 300 MHz, and -20 dB at 1 GHz.
$.50 each, $1.00 for 3 pieces. ***ONLY 36 PIECES REMAINING***
***
Air-variable capacitors manufactured by Cardwell (their part no.
PL6348).
NOS surplus, m'fd. sometime in the 1950s.
--Configuration: consists of two plates separated by 0.1";
--Estimated capacitance range: 1-5 pf.
The adjustment shaft is 0.25" dia. by 0.5 inches long; bushing or
isolated mounting; easily disassembled for capacitance vs. frequency
modification, etc. A more-detailed description is available on request.

Price: $1.00 each, $10.00 for 12 pieces
***
Caddock MS281N NONINDUCTIVE resistors:

10 ohm +/- 5 per cent tolerance, 8 watt noninductive power film
resistors
Tinned axial leads (0.75 inches long) are formed for PC-board
insertion on 1.2-inch centers. These are NOS, bulk-packed parts.
Note: these measure well within tolerance at +/- 0.2 ohms typical. Full
specs are available in PDF format on Caddock's web site
(www.caddock.com)
but highlights are:
--Temperature coefficient of resistance: 50 ppm;
--Power rating: 8 watts at 25 C, derating to 4 watts at 150 C and
0 watts at 275 C;
--Noninductive design: serpentine film layout cancels magnetic field-
equivalent inductance of a straight piece of wire of the

resistor's body plus lead length.

Applications include:
--Current sampling;
--Cathode bias;
--Dummy loads for audio and RF applications.

Price: $1.00 each ($10.00 for 12 pieces); only 70 pieces available
****
****
* NOS Warranty policy *
****
Scanned images or digital photos of components are available on request.

If you purchase NOS tubes or components and find them unsatisfactory upon your inspection, notify me within seven days and return items in as-received condition for a full refund or replacement (if available).

This material is subject to prior sale and is supplied as-is, as new-old-stock (NOS) merchandise, with all responsibility for safe and successful application residing solely with the purchaser.

If you're searching for oddball components of any vintage, don't hesitate to inquire about availability.

Source record: 62047

I have a surplus Collins filter in my junkbox. According to the markings

it is for 420 kHz and somewhat larger than those filters I am familiar
with
(L = 3", DIA = 3/4"). Does anyone have any further information on this
type of an filter; in the WEB I have not found any models for this
frequency.

Thanks,

Heikki Ahola (OH 2 LZI)

And do you mind if I ask what is your basis for the claim that "Only
after all other explanations are exhausted, is it time to consider
new ones?"

Isn't that that "Horganism" that that other poster was talking
about? How do we find the new ones if we confine ourselves to
the box of what's "already known?" There's skeptics, and then
there's those who claim to be "skeptics," but simply discount
everything outside their little box. I have at least one
example, but since it doesn't fit into most people's pre-
defined paradigm, and it involves challenging that paradigm,
the pseudo-skeptics and Horgans will dismiss it out of hand.

I call it brain lock. (the phenomenon of rejecting what they
don't already know, that is. Brain lock isn't the example of
my new information outside the "box.")

Cheers!
Rich

Perhaps a generalized lens. The notion of a slab
indicates to me that it was flat and not an ordinary
curved lens. But a zone plate is flat and has
concentric rings of alternating properties
(usually attenuation, but could be phase shift).
Use the right monochromatic light, and it will
focus.

Anyway, the original was discussing microwaves,
which are usually generated in a fairly narrow
band, so its not surprising that it could be
focused with a structure of alternating properties
such as copper and air.

Opinions expressed herein are my own and may not represent those of my employer.

2447. Re: One tube regen tuning circuit question

Newsgroup: rec.radio.amateur.homebrew

Source record: 62055

The 15 pF capacitor is the bandspread. Chances are you want to put the vernier on the main tuning capacitor, the 100 pF but that depends. Since the ratio of the capacitors is about 7 to 1, putting the vernier on the main tuning will make it about the same tuning rate as the bandspread. If you put it on the bandspread you will get some mighty fine tuning.

Regenerative receivers aren't very stable so you will be correcting for drift as well as finding how adjusting the amount of regeneration affects the frequency. Make sure to build it solidly and keep the heat of the tube away from the tuning components. And if you are using a speaker, don't mount it on the same chassis. If possible, use a regulated power supply.

73, Bob K6DDX

The 100pf would be the band set and the 15 would be the band spread. Opinions may vary on which cap to put the reduction drive on. It may depend on how selective a radio you are building. If you only listen to AM stations put the drive on the 100pf and you might get away with omitting the 15pf cap. If you are shooting for razor sharp selectivity and want to listen to CW and SSB then I would put it on the 15pf cap. Good luck on your project and let us know how it works out. Regens can be pretty amazing. 73.

A distraacted Rich Grise made these comments
>concerning Re: "energy sucking" simplified:

>And do you mind if I ask what is your basis for the claim that "Only
>after all other explanations are exhausted, is it time to consider
>new ones?"
>

If something can be explained by the existing theory,
how do you propose to use it to obtain a theory that is
different but not equivalent.

>about? How do we find the new ones if we confine ourselves to
>the box of what's "already known?" There's skeptics, and then

By finding phenomena that dont fit any existing explanation
as I already stated. Why are you asking something to which
you even restated my answer in the sentence you wrote before
this one?

>there's those who claim to be "skeptics," but simply discount
>everything outside their little box. I have at least one
>example, but since it doesn't fit into most people's pre-
>defined paradigm, and it involves challenging that paradigm,
>the pseudo-skeptics and Horgans will dismiss it out of hand.
>

Or in other words, because you have a limited understanding
E&M, you think it's prudent to just invent a new explanation
despite the fact that you dont have anything that a better
understanding of E&M wouldnt explain.

>I call it brain lock. (the phenomenon of rejecting what they

Yeah. Another term is "wishful thinking". See pons and fleischman
on cold fusion or bockris on transmuting elements.

>don't already know, that is. Brain lock isn't the example of
>my new information outside the "box.")

If quantum teleportation was taken seriously, and it was,
then you have an example of a rather exotic phenomenon that
until then was considered dubious at best, but because it
was shown RIGOROUSLY to exist, it wasn't considered whacko.
You apparently live in a small box where many phenomena
are outside of your understanding. Your limitations dont

apply to everyone, not all of us are so confined as to
need magik to explain things.

Hi Ed,

OK, I had suspected you were wanting to use the amp on an antenna. I've seen diagrams for what should be very good balanced JFET preamps to do just the job you want. Wish I could remember just where! I think it was on the web on one of the ham related sites, but it might also have been an "Ideas for Design" in Electronic Design or EDN magazine. I'd say you want to connect your JFET gates directly to the antenna coupling loop, in a balanced fashion, maybe with some diode protection in case someone transmits nearby. Even just using them as followers should be OK, as I'd expect you're not hurting for signal voltage, if you keep the preamp input impedance high enough. Once you get to a low impedance, then a balun has a much better chance of doing some good. There are plenty of ways to trim the balance. I really don't think you want to try to do an RF-bandwidth instrumentation amplifier with op amps, because of the cost of really suitable op amps. The circuit I'm thinking of, I believe, was powered through a simple DC superimpsed on a coaxial feedline. Also, I think there's some good food for thought in the antenna engineering books about how and why to keep things symmetrical (balanced) in a small receiving loop...I might have a set of .gif files at home of scans of a few pages of one ref I like a lot, if you're interested.

Cheers,
Tom

It is a comparison of the forward and reflected RF voltages.
Two seperate rectifier diodes convert the RF into DC voltage, which drives
the meter movement to a level that is calibrated be resistors on the meters
circuit board.
the forward reading is compared to the reflected level, to get the SWR
reading.

The key to this is a dual directional coupler.
The coupler has a mainline, which connects the rig to the antenna.
It also has a forward port, and a reverse port.
Suppose you have a 100 watt signal with a 40/40 dB coupler.
The forward port would pick up 100 watts (50 dBm) minus 40 dB, which is 10 dBm, or 10 mW.
The reverse port would pick up nothing if the coupler directivity was perfect, and the load is perfect.
If you unplug the antenna, all of the signal would reflect back to the reverse port, and you would
read the 10 mW.
But let's suppose that your antenna VSWR is 1:1.5, or a 14 dB return loss.
This would reflect back 50 dBm - 14 dB minus 40 dB, which is - 4 dBm or 400 uW.

As Matt indicated, you just peak detect the two ports with a diode and filter cap, and compare
their values on two meter movements, or by using a single meter movement, you adjust the forward
port to the cal position, and switch to the reverse position.

Good luck Andreas. You will find that you can easily build your own dual directional coupler simply
with a copper circuit board and an Exacto knife.
Al

Since this topic is being discussed on Bill's science list, I thought I would throw my 2-cents in here for your comment:

>If I recall, the speed of propagation (group velocity?) is the square root of the product of the permittivity and the permeability. So, if they are both negative, then the product will still be positive. Whether or not this was faster than light in a vacuum would depend on the magnitudes of the permittivity and the permeability, not their sign.

>I gather that it is quite possible for the phase velocity in certain transmission lines to be faster than light at certain frequencies. I have heard that you can actually measure this, by measuring the frequency and wavelength of standing waves of that frequency.

>I have never quite understood the argument that this does not mean that you can transmit real information faster than light down such a line, since real information has a multitude of frequencies, each of which travels at a different speed. They say that it has something to do with what is called group velocity.

>Does anyone out there have a good picture or analogy to explain the difference between group velocity and phase velocity?

If you got to the LLNL server (search for evanescent or superluminal or waveguide or something) you can find some very scientific papers that describe the superluminal (faster than light) 'evanescent' wave through a microwave waveguide, that has a choked section in the middle, which functions as a high-pass filter.

This high-pass filter attenuates the low frequencies more than the high, and through the miracle of the fourier transform, deludes math-impaired scientists into believing in superluminal waves (unless the are sitting back giggling at all the niave lamerz they are foolin). After perousing these LLNL papers I did a Deja search, and found some very good explanations.

Consider what happens if you generate a modulated microwave pulse and send it through the choked, high pass filter, waveguide. Measure the transmitted pulse in its middle. The received pulse is distorted and narrower because the low-frequency components have been reduced in amplitude. So you measure the center of the pulse again, and find it has traveled apparently superluminaly. NOT! It has traveled at the characteristic phase velocity, you've just changed at what point you measure. The fourier transform does this mathematicaly.

BTW an evanescent wave is a type of tunneling. The microwave signal is greatly attentuated by the above-cutoff section of choked waveguide. If you

place two prisms or optic fibers very near (nanometers), photons will 'tunnel' across the distance. The electric and magnetic fields interact. And also (I believe anyways) if particles are soliton-like entities, they are distorted by radiation and radiation reaction, which allows them to tunnel across potential barriers. An LLNL paper by Vlassov describes this.

I'm think the phenomena of negative permitivity/permiability is just a fancy array of phase-shifting microstrips in a dielectric, a sort of photonic crystal, or phased array LC network.

Scott

John Woodgate made these comments concerning "energy sucking"
simplified- Round 2:

>I would hope to see a material in which the permeability and
>permittivity are of opposite sign, because the speed of light in such a
>material would be imaginary.

That's OK. It means the indec of refraction is imaginary and
light doesn't propagate. The permittivity is, in general a
complex function of frequency. You could appeal to snells
law to get n1 sin(\theta1) = (n2*) sin(\theta2) and if
n2* = i (n2) , (n2*) sin == n2 sinh.

I like to view SWR meters as impedance ratio meters. They indicate the ratio of the impedance of the line/load at the point they are placed in the line compared to the design impedance of the meter(usually 50 ohms).

2471. Re: How does an SWR-Meter work?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-25 00:00:00 UTC
From: Carl Clawson <cclawson@transport.com>
Message-ID: <1KbD4.170$6S6.26774@tw11.nn.bcandid.com>
Source record: 62001

The SWR can be measured on a uniform line by measuring forward and reverse powers at a single point in the line. This can be done with directional couplers, or by independently measuring current and voltage at that point. I'll write down the math for the latter if anyone wants to see it.

Matt's explanation was just fine. And you can certainly do the measurement as described below, but it's not the only way. Such an instrument does exist; it's known as a slotted line. They're used at UHF and microwave frequencies, but are not practical at HF.

The problem with SWR meters that we can afford is one of accuracy, not that there is any fundamental difficulty defining SWR in terms of measurements at one point in a line. I'll agree that if a line is extremely short (length/diameter not large) then impedance and SWR are ill-defined.

Regard, Carl WS7L

2472. Schematic needed Harrison 6240A Power Supply

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-25 00:00:00 UTC
From: Solomon Fernblatt <badger@telalink.net>
Message-ID: <DRdD4.14283$s65.86172@news2.atl>
Source record: 62002
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment,rec.radio.amateur.misc,sci.electronics.equipment

Found a small benchtop power supply today at a local
hamfest. It is a Harrison (later HP) model 6240A.
Anyone know of a source for info on this oldie? It seems
to be working fine, but would be nice to have a schematic.
Please reply directly to the email address below.

Thanks for any help

Tom KA4RKT
Badger@telalink.net

OK, here's one attempt at a rational response to one thing you've cited:
(please see below, just after item 3.)

William Beaty wrote:

My comment on this is that yes, in the diagrams on that page, you'd
probably get a pretty respectable power transmission rate, but my
counterargument is that the receiver is entirely embedded in the
dielectric of the large outer capacitor. I think this is how Tesla
achieved wireless power transmission.

Now, if you could figure out a way to turn the whole ionosphere into
one electrode of a global capacitor.....

Good Luck!
Rich

So, if you subscribe to the "Quantum-Wave Function" theory of photons,
then
for efficient transmission of power, all you need is a "Photon
Collapser,"
or maye a "Quiff Catcher." ("QWF"). Since a photon is a QWF until it's
detected
somewhere, then the whole thing collapses instantenously into a
detectable
photon. Just capture them all, and you're home free!

Cheers!
Rich

2482. Re: How does an SWR-Meter work?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-25 00:00:00 UTC
From: Reg Edwards <G4fgq.Regp@btinternet.com>
Message-ID: <8bh1b7$fe2$1@plutonium.btinternet.com>
Source record: 62071

Dear Andreas,

First thing to remember there is no such thing as a genuine SWR meter.
Beware of adverts.

Such a theoretical meter measures the ratio of the voltages (or
currents) at two different places along a transmission line spaced
1/4-wave apart. Unless such a meter has simultaneous access to these
two different locations along the line then it cannot indicate SWR.
And as you may already be aware, the common or garden SWR meter has
access only to one location on the line - the place where it is
fitted.

The location in the line of the usual SWR meter, ie., immediately at
the output of the transmitter, actually indicates the SWR on a
non-existent line - ie., the non-existent line between the meter and
the transmitter.

How can a line of zero, or even very short length, have standing waves
?

Since you are just taking a ratio, it might be accurate enough.
As a sanity check, you can measure the SWR normally. Then, reverse the mainline input/output connections.
You should see the same readings, but swap the forward for reverse.
If they don't agree, then something is wrong.
Al

Another mystery to me is the many messages which essentially
say "uh, you know that this doesn't CREATE any energy,
right?" Well, yes, why would I think otherwise?

Is there something weird about sci.physics.electromag,
where whenever someone starts explaining antennas in an
odd way, everyone suddenly assumes that perpetual motion
machines are being discussed?

Or is it because of OTHER stuff on my Weird Sci. website?
I've never brought up the topic of pertetual motion or
violations of COE in this discussion. I don't quite
see why others continue to do so.

If an antenna absorbs energy from a wave, it's not
perpetual motion. If an extremely small antenna absorbs
EM energy as if that antenna was electrically much larger
than its physical size, in what way is this a claim
that a perpetual motion machine is possible?

Or is N. Tesla the problem? Tesla was trying to broadcast
significant power across great distances. Many members
of the general public imagine that this was some sort
of perpetual motion scheme. If such thinking has gone
on for long enough, then perhaps whenever somebody even
MENTIONS the word "Tesla", skeptics assume that perpetual
motion machines are being claimed. But if they do so,
then they are making a mistake, and perhaps they would
do well to actually read what the messages say.

Exactly. Or along similar lines: if you make the antenna TOO
small, then there's no way it can work in practice, because
we lack appropriate materials. (But just wait awhile and see
if low-cost room-temp superconductors eventually make some
"energy sucking" applications a bit more feasible.)

> per cent efficient dipole.

This is lower than I expected, but not THAT much lower.
As I've been saying, it is the principle that fascinates
me the most. And the fact that it isn't generally discussed
in electronics mags, and the fact that I had always believed
that the LC circuit in a crystal radio was only there as
a bandpass filter. How many here were already aware that
the LC circuit in a crystal radio is almost essential to
proper operation? It makes the antenna grab more waves!
Or if you insist, it acts as an inverse impedance
transformer. But if you thought as I did that its only
function was to eliminate unwanted AM stations from the
audio output, then you are missing something interesting.

If an antenna can be made essentially lossless, then the
"energy sucking" effect becomes much more important...
and if we apply these wave-based ideas to interactions
of EM waves with atoms and molecules, we might notice
some things which have not been so obvious from a photon-
based viewpoint.

For example, if two molecules are widely separated, yet
they both have a resonance where the wavelength of
the radiation puts them within 1/4 wavelength of each
other... then any EM waves emitted by one molecule
can be largely intercepted by the other. If molecules
behave like LC resonators which have zero internal losses,
then widely-separated molecules can "talk" to each other
through their mutual AC fields at their mutual resonance
frequency.

If the physics paper in Soviet Physics is correct in
pointing out that this "energy sucking" phenomenon
is part of stimulated emission... then adjacent
molecules might be able to interact in
interesting ways. Maybe a form of "logic switching"
or simple computation can be performed with arrays
of molecules having identical resonance frequencies.
This would be a Quantum Computer, if I understand
the concept. It would really be cool if some of the
mysterious structures in protein molecules turned out
to perform quantum computations using "energy sucking"
as their mode of inter-node communications. Just
because two molecules are not in direct contact, it
doesn't mean that they cannot have significant effects
upon each other.

> In my opinion, making an antenna part of a high-Q resonator provides
no
> special properties above and beyond fulfilling (at least partially)
the
> circuit requirements for achieving maximum power transfer to the load.

Of course. The people who keep implying that "energy
sucking" is wrong in principle are making a big mistake.
Better that they should say it's boring and well known, than
trying to defeat the idea on the grounds that it violates
some part of physics or another.

The interesting part (from my viewpoint) is to
apply this piece of antenna theory to the molecular scale,
and see if it exposes any new ideas which were made obscure
when everyone thinks in terms of photons rather than EM
wave propagation.

And maybe I'll try running some flashlights and electric
shavers in my home by wrapping a big transmitter loop
around the house, and driving it with 30KHz or so.
I wonder how small a hi-Q antenna can be made, yet
still light a flashlight bulb when near a large loop
being driven with a couple of amps at 30KHz? Put it
in a plastic flashlight, or inside a toy robot?

AHA! NO WONDER people keep complaining. I didn't realize
that everyone was seeing that and leaping to incorrect
conclusions.

I run a huge website on Amateur Science, but also one on
Crackpot Science as well, including large email-forums
dedicated to each. To ensure that the two remain
separate, and that there is no question about which
articles are serious and which are weird stuff, the headers
in the crackpot side have those keywords, and that includes
most everything in the Tesla Coil section. I copied a page
in the Tesla Coil section when I made the nearfld1.html file.

> and claims that space is nonlinear with respect to EM propagation,
> it's bound to cause some skepticism and -dare I say it- hostility
> among people who actually try to design electronics that works.

I shouldn't have used the word "nonlinear", although at
the time it seemed quite appropriate. What looked
"nonlinear" to me was the E/M ratio in the nearfield
region of the antenna. The fields there need not be
perpendicular, nor have a 377 ohm ratio, yet those
fields are proportional to the intensity of incoming
radiation (you might even say that they are created
by that radiation). The nearfield region does not
match the impedance of free space, at least for waves
at the resonance frequency. From the viewpoint of an
EM wave, the nearfield of an antenna is a reflector/
absorber object! Or as others keep insisting, it is
simply an impedance mismatch. But when light hits a
glass prism, the air/glass interface is a "nonlinear"
step, even though the EM equations are still "linear."
(And in the case of an air/glass interface, WHERE
exactly is the "step"? Isn't it spread out over
1/4 wavelength on either side of the interface?
Think in terms of the evanscent waves in the air

when light suffers internal reflection within glass.)

> There is of course a 'hidden gotcha' in your scheme.

Which one? The lossless coil?

> two 1 farad capacitors, one charged to 2 volts, the other at zero.

I'm well aware of that one. Physics teachers commonly
use it as a trick question on final exams (for extra credit
only, if their hearts are in the right place.)

> What happens when they are paralleled? If both wind up at 1 volt, as
> circuit theory predicts, then where did the energy go?

It oscillates as a one-turn inductor with the two
capacitors, and either heats the wires and capacitor
dielectric, or if this is just a thought experiment,
oscillates forever or perhaps radiates its energy away.

> The gotcha is that the small capacitors are not lumped capacitors,
> they are regions of space. An AC current flowing in space creates a
> magnetic field, and the combination can merrily propagate away (as
> James Clerk Maxwell so cleverly predicted), and one manifestation of
> that is called 'radiation resistance'.

It's certainly not hidden. I chose the long wavelength,
with the metal plates being a couple feet apart, running
at 500KHZ, so farfield effects would be minimized in
that example.
(Maybe I should have said 10KHz to make certain people
knew it was in the nearfield? But look at the title of
that article! NEARFIELD COUPLING AND TUNED CIRCUITS.)

In the tesceive.html article, the issue is not as simple,
but the analogy still is very close.

Tesla intended to exite the earth/ionosphere waveguide as
a resonant cavity. In that case both the transmitter and
the receiver see multiple images of each other, an overall
standing wave develops, and the coupling between widely
separate emitters and absorbers is very much like nearfield
coupling between a pair of adjacent antennas. In a resonant
cavity, when an absorber is tuned to the same frequency as
the emitter, the emitter "feels" the presence of the absorber.
The global standing wave becomes less when an absorber suddenly
appears... very much like when the two are within 1/4
wavelength of each other.

> In your example, you assumed the small capacitors were ideal
> components. They actually approach ideal if the H-component of the

> system can be 'frozen out', which can be done by making the frequency

> innards of the plates into a waveguide-below-cutoff at the frequency
> in use, or, equivalently, by moving the C2 plates *very* close to the
> big plates. These conditions do not prevail in the farfield case.

Obviously. That's why that website is "nearfld1.html."
That's why I instruct the reader to imagine that the plates
are a couple of feet across while the 500KHz operating
frequency is 600 meters.

> Besides, millions of professional and amateur radio designers have
> been tuning all sorts of bizarre antennas for nearly a hundred years
> now, and surely somebody would have discovered energy sucking by now
> (or maybe they did, and do, but the Black Helicopters always come and
> get 'em.)

Now I don't understand. If I continually claim that
"energy sucking" is entirely conventional, electrically-
small resonators, and you now say that amateurs don't
know that "energy sucking" exists (meaning, they don't
know that electrically small antennas can gather significant
energy if a resonator is added), then I can't make head nor
tail of the conversation.

Or perhaps you are assuming that I think "energy sucking"
violates conservation of energy? Others keep ACCUSING me
of thinking that, but if you read my posts, you'll see that
this is a straw-man argument being used by others to argue
against the importance of the electrically-small resonant
antenna concept! It's really silly. To defeat the
horrible crackpot who insists that this interesting effect
is part of conventional EM, they attack some totally
conventional science and try to prove that it is crackpottery
which is impossible even in principle.

If this confusion is caused by my OTHER weird-science article
about rotating domains in a ferrite ring, with a tuned
circuit extracting energy from nowhere... then I understand
the origin of the confusion. I'm not talking about that
article, I'm concentrating on the "tesceive.html" and the
"nearfld1.html" articles. Also, that article about the
"free energy device" involves far more than just conventional
antenna physics. If there is anything weird to be discovered
there, it involves coherent Barkhausen noise from domain-
flipping in magnetic materials. Ahem... NONLINEAR stuff. :)

> (Oops, didn't mean to seem too sarcastic, but you know the temptations
> of the Internet.) Really, you should study some electromagnetics to
> see what's going on here. You know, in many colleges nowadays, you can
> get an EE degree *without* taking a course in electromagnetics; that,
> to me, is more frightening than Black Helicopters.

I guess I'm found out. When others here launched a vehement attack with all sorts of nasty assumptions about my nature, I decided not to "defend" myself by mentioning that I'm a BSEE (for 20 years now), took all the requisite waves/fields/undergrad-phys courses, am a physics fanatic at the hobbyist level, consult on science textbooks occasionally, write project articles for a kids science webpage, hang out on PHYS-L the college physics education forum, play "science guy" for the MADSCI project, and my passion in life is to construct physics explanations which can be understood even by grade school teachers. Hence all my non-math mental models and visual representations. For a REAL challenge in physics, try explaining it to your grandmother! There's an Einstein quote about that. For a sample of my work, see:

KID'S SCIENCE PROJECTS
http://www.halcyon.com/sciclub/kidproj1.html

EXPLAINING ELECTRICITY SO PEOPLE CAN UNDERSTAND IT
http://www.amasci.com/ele-edu.html

SCIENCE ANSWERS (MADSCI PROJECT)
http://www.amasci.com/amateur/answers1.html

MISCONCEPTIONS SPREAD BY K-6 SCIENCE TEXTS
http://www.amasci.com/miscon/miscon.html

Especially take a look at HAND-DRAWN HOLOGRAPHY in the kids' science project section. Truely strange, yet entirely contained within conventional geometrical optics. (I should get a flamewar started here about whether it is *really* holography or not.)

But with all that, I never encountered the idea that a small resonator can generate a field, and hence absorb fairly long EM waves by cancelling them via superposition. Like the authors of those two physics papers, I found the idea to be fairly intriguing.

And yes, I love the crackpot stuff and maintain a large section of my amateur science site dedicated to it. After all, we crackpots count Goddard and the Wright Brothers among our number. Mainstream science is still embarassed by the fact that modern aerodynamics was founded by widely-reviled flying machine crackpots associated with no academic institutions. Me, I'm waiting for a crackpot in his/her basement to come up with a genuine "antigravity" engine. If that ever happens, it will "destroy science", meaning that physicists will never live it down! :)

Nope, the story described some sort of black box device
sitting on a table. Before coming to understand what
tuned-primary tuned-secondary transformers can do, I
assumed the story was just fantasy.

Hey, maybe it was a really OLD dorm, with knob-and-tube wiring.
My own home is from 1925, and a small probe-coil shows that the
whole place is saturated with 60Hz b-field (and harmonics from
a couple of light dimmers.) In the living room, the "hot"
wires run across the ceiling and down to the outlets, then
the neutrals continue down into the basement. If this was
typical for very old structures, then perhaps it isn't ridiculous
to try to couple a 60Hz "tuned secondary" to the one-turn
primary in the walls. Especially if somebody has an electric
heater turned on somewhere.

A distraacted Science Hobbyist made these comments concerning
> Re: DOH! My big "energy sucking" error!:

> Another mystery to me is the many messages which essentially
> say "uh, you know that this doesn't CREATE any energy,
> right?" Well, yes, why would I think otherwise?
>

For one thing, it's the "natural" way to circumvent having to
explain your way out of having so many of these "antennas",
that you have an effective "surface area" greater than 4*pi.
If your "antenna" were to really do what you think and cover
a larger solid angle than it physically subtends, you would
leave holes when minimally covering 4*pi, and after that you
cover the same area twice or more. Other ways around it aren't
any more convincining.

> Is there something weird about sci.physics.electromag,
> where whenever someone starts explaining antennas in an
> odd way, everyone suddenly assumes that perpetual motion
> machines are being discussed?
>
Only if it does, in which case, it's a good argument. Science
is the business of invalidation since a positive proof for a
theory is impossible. Once you find a point that two explanations
contradict each other, one has to be incorrect. If that point
happens to involve conserving energy, why look for a really
obscure principle for a conntradiction?

> violations of COE in this discussion. I don't quite
> see why others continue to do so.
>
If the topic you post brings it up implicitly, then
you've brought it up, whether you intend to or not.

> If an antenna absorbs energy from a wave, it's not
> perpetual motion. If an extremely small antenna absorbs
> EM energy as if that antenna was electrically much larger
> than its physical size, in what way is this a claim
> that a perpetual motion machine is possible?
>
Depends upon what you mean by absorb. Since you dont
believe energy that isn't absorbed is re-radiated,
but choose to believe the antenna somehow absorbs
radiation from the space around it in a way that isn't

adequately addressed by a probability distribution
which doesn't have the problem of covering more space
than there is to cover, I don't see how you can avoid
that problem. If your antenna acts 50 % larger than
it physically is, how much radiation does each antenna
absorb if you use a sufficient number to completely cover
4*pi, and hence the entire flux? According to your
procedure for optimizing, you should recover the
optimal result by retuning for resonance. Nothing
prevents that. So, you are stuck with explaining how
the energy received by the antenna can be larger than
the solid angle it subtends /4*pi while insuring no
more than what is radiated into 4*pi is ever absorbed.

> Or is N. Tesla the problem? Tesla was trying to broadcast
> significant power across great distances. Many members
> of the general public imagine that this was some sort

I personally cant remeber saying anything one way or another
regarding tesla, since I don't know much about him, nor can
I recall him being the foca;l point or reason for rejecting
anything. For some reason, people seem to invoke his name
in association with a lot of things that are kooky that
he probably had no part of in a bid to win sympathy as a
"misunderstood genius" for some self-seving purpose.
In most cases, it probably is a favor to tesla to discredit
such kookiness and misuse of his name.

> then they are making a mistake, and perhaps they would
> do well to actually read what the messages say.
>

This is not unusual. Near a resonance in the material the permittivity becomes complex, and the real part can go negative. The "speed of light" in this sense is the phase velocity, and for it to be imaginary (or complex) means only that the material either absorbs or amplifies the signal, depending on the sign of the imaginary part. Signal propagation velocity remains boringly less than the vacuum speed of light, although the usual concept of group velocity becomes kind of complicated. Look in an electromagnetics book under "anomalous dispersion" to read further, for example J.D Jackson, Classical Electrodynamics, 2nd ed, chapter 7.

Lyle Koehler made these comments concerning
>Re: "energy sucking" simplified:
>
>The "effective area" of an antenna is equal to G*(wavelength
>squared)/(4*Pi), where G is the directive "gain". For a very small
>dipole, G is 1.5. Multiply this area by the incident power density and
>you know how much power is theoretically available from the antenna

I'm going to elaborate on the directivity here, so it doesnt give
the impression that it actually do anything mysterious. The directivity
factor only occurrs because the radiation pattern for a dipole is NOT
isotropic and no one would use a dipole in a way that didnt take advantage
of the angular distribution. What you gain from directivity, you lose
once you are much off the axis of the lobe.

If you integrate dP/d\Omega over 4*pi, you'll get the same answer
of Power radiated <= Power supplied regardless of what antenna
is used. The efficiency will never be larger that 100% and all
antennas with the same radiation efficiency will give the same
value for that integral over 4*pi.

>terminals. This area is much greater than the physical size of the

Sure. You've first turned your antenna into an isotropic
source and then compensated for it by making it bigger
to account for the anisotropy. Since it wont be used in a
manner that takes disadvanage of the anisotropy, you neglect
that the points way off axis of the lobe will be much "smaller",
so-to-speak.

>antenna, which causes a lot of confusion even among people who claim to
>be antenna experts. In practice, only a small amount of the

As you've noted, this apparently leads to confusion, so why not
use a more realistic expression for dP/d\omega? Then you can use
the power that's REALLY available rather than restating in terms
of directivity? This is the same thing that in physics would
be called a form factor in a scattering cross-section.

>Here is a sample calculation of energy capture from a 50 kW, 500 kHz
>station at 10 km, using "conventional" antenna theory. The effective
>area of a small dipole at 500 kHz is about 43,000 square meters, and in
>free space the power density from a 50 kW station at 10 km would be
>about 0.00004 watts per meter. The theoretical maximum power available

This isn't quite correct. For a dipole, you do not radiate that 50 kW
isotropically. The actual power available at that distance for
any given area depends upon the angular position about which
the area is located on the sphere. That 0.00004 watts/m^2 assumes
50 kW radiated isotropically into 4*pi at 10 km through a 1 m^2
area. For a dipole, dP/d\Omega is prop. to sin^(\theta) not 1, so
for example, a small circular area (actually asmall section of the
sphere) of angular size {\Delta\theta/over 2} you get a very different
answer for \theta = [0, {\Delta\theta\over 2}] than you get for
the same size patch at [{(pi -\Delta\theta)\over 2}, \pi].

> in a plastic flashlight, or inside a toy robot?

The theory and practical details of this are quite well-established. E-
mail me if you want to know more. It isn't as easy as it appears - one
problem is that you loop has significant inductance and you will need a
lot of volts to drive 2 A at 30 kHz. Unless you make the resistance of
comparable value to the inductive reactance (thus requiring even more
volts), the load power factor is abysmal and the sending-end efficiency
is also abysmal. Also, the loop radiates: the field is by no means
confined to the inside of the loop.

G'day Calvin,
You could try one of the homebrew sites available on the net(try your favourite search engine for "amateur radio") or I can recommend this site to you:
http://home.alphalink.com.au/~parkerp/
This is a site packed with useful info, projects and links.
Good Luck,
Glenn.

Would have worked too, except for the safety concerns .. (lots of RF power flying around) .. not to mention not being able to use radio at many frequencies ...

Maybe directed microwaves would have been better .. (more concentrated beam) ... better still, multi-megawatt laser beam at suitabe frequency.

I'm glad that you mentioned your qualification, because it was clear to me that you were qualified but that there are odd lacunae in your knowledge. It happens. A certain very well-qualified person in a very responsible technical position determined that a 'neck-loop' (a sending coil for use with hearing aids that have a 'telecoil' magnetic pickup, much more common in Europe than USA) requires a 10 W amplifier to drive it whereas the correct value is about 50 mW!

The properties of small tuned antennas were determined more or less empirically a very long time ago - I don't have time or inclination to turn up Lodge's paper(s) on 'syntony' (tuning) but I wouldn't be surprised if it's in there somewhere. If not, probably in Marconi's papers. The explanation by superposition and interference may be new but ISTR MG Scroggie ('Cathode Ray') explaining ferrite rod (loopstick) antennas that way, back in 1950 when they were new.

Yes, there can be no objection to people indulging in 'crackpot science' if they want to, and there is a potential for new discoveries to be made that way. ('Basic research is what I do when I don't know what I am doing.' - Werner von Braun) What is not so acceptable is people (not William Beatty) persistently trying to ram their unfinished or easily disproved ideas into unwilling ears, and screaming 'suppression' when

they can't publish at someone else's expense. Especially these days,
when it is EASY for anyone to publish their own work at very low cost.

When you say 'saturated' I suppose you mean 'permeated' - I'm not trying
to reduce this to semantics but to show that such a device is
practicable you must *quantify* the field strength.

> In the living room, the "hot"
> wires run across the ceiling and down to the outlets, then

> heater turned on somewhere.
>
Yes, the 'go' and 'return' paths would have to be widely separated. It's
quite easy to calculate the field strength produced by the primary, but
the most practicable secondary is a solenoid with a nickel-iron core,

and it is difficult to calculate both the inductance and the 'rod permeability' (flux-concentrating factor) of such a device. Tuning it would certainly improve the results greatly.

I notice that you first wrote 'small flashlight bulb'. Yes, you might just be able to do that, with a costly solenoid (lots of nickel-iron!). It would be impracticable to work the 'light bulb' (120V 50 W?) that you mentioned later.

Depending on whether permittivity or permeability of space becomes
negative, space becomes either a low-pass or high-pass filter beyond
cut off. In either case there's no propagation. But no need to worry.
The reason we are here is because it never happens.

Well, I'd have used the term, "Magick," but I don't think they're
the same thing, albeit both are outside the current paradigm.
But I think they're either different directions or different
dimensions.

In either case, it would seem there's a lot of work to do to
come up with repeatable technology that works. "Orgone" is
another thing I'd like to investigate. How does one go about
getting a research grant?

Cheers!
Rich

Hello HAMs ;-)

Thank you for your answers. I think I know how an directional coupler works. The problem is the geometric dimension. At VHF, UHF and so on, it will work fine. But at Shortwave? Carl wrote anything about 'independently measuring current and voltage at that point' (see below). I know some SWR-Meters, where the line goes through an 'transformer'. Are these of this type? My original question concerned such SWR-Meters. Sorry :-) I hope you know what I mean. And Carl, if you mean this kind of SWR-Meter, I am interested in the mathematics. Thank you.

tnx, 73 de Andreas.

==========
Sorry to disagree. They do not indicate an impedance ratio. If one impedance is 50 ohms resistive and the other is 50 ohms reactive then the indicated ratio will not 1 but infinity.

The common or garden SWR meter actually indicates the unbalance voltage in a bridge where the standard arm of the bridge is a resistance of 50 ohms. It so happens the unbalance voltage is directly proportional to the reflection coefficient with respect to 50 ohms.

The magnitude of the Ref.Coeff can vary between 0 and 1. However the meter does not indicate the phase angle of the RC which is just as important as the magnitude. Half the information is discarded !

Nevertheless, a more appropriate name for the instrument is "Reflection Coefficient Bridge".

Well, there's always the "smoke test".

The only other solution seems to be to have a large stack of toroid data sheets from various manufacturers, and to try and match the measured AL, Q, dimensions and even paint colours to some identifiable product.

From: Mike Monett <mrmonett@yahoo.com>
Message-ID: <38DE69A5.577E@yahoo.com>
Source record: 62026

I have been studying Shannon's paper, and how he develops Gaussian noise and relates it to the information capacity of a channel.

Passing wideband noise through a narrow-band filter would change the maximum rate of change of Gaussian noise, the same as it changes the information capacity of a channel. In other words, the autocorrelation is no longer zero for all t.

It may be that the sampler, which depends on the randomness of noise to reject it, may find the Gaussian noise is no longer random enough from sample-to-sample to provide the same rejection capability.

The only way to show this is to generate bandwidth-limited Gaussian noise, and use it in the simulation. This would be very slow in conventional simulators.

Fortunately, I have the software framework already to do this, and will proceed.

Even so, the sampler/mixer has other very useful properties.

And not many people get a crack at Shannon in their lifetime!

Well, in picofarads it's 1.13 (actually 36*pi/100) times the radius in
centimetres. So 707 uF is credible. BUT that's not the capacitance
between the ionosphere and the solid surface. I can't turn up the
formula for the capacitance between concentric spheres at this moment.

I vote with the larger cap (100pF) as the Main Tuning control. You did not mention if the 5:1 Reduction drive was part of a vernier dial assembly, or just the reduction drive. I "modified" an Ocean Hopper some time back (40 years?) with a vernier dial with a healthy ratio. That allowed me to "log" my settings for subsequent retunes - difficult with the standard 0-100 dial. The added benefit was that I seldom had to use the fine tuning as the vernier had the same tuning ability. It did allow me to set on my XTAL freq and then tune either side a few KCs.

> me that you were qualified but that there are odd lacunae in your
> knowledge. It happens.

It's totally expected, especially in view of the fact that
digital is my specialty. I get my nose rubbed in reflections
at impedance mismatches, but everything is broadband,
and I'm never forced to confront many details about analog,
or to think about how antennas REALLY work.

What got me going was the fact that I've seen many,
many explanations of crystal radios, but I've NEVER
seen anyone explain their LC circuit as being anything
but a bandpass filter. According to such thinking, the
LC circuit is just a nicety, and without it, a crystal radio
would pick up ALL strong stations. But it certainly
doesn't work that way if you try building one.

And I've never deeply understood the operation of
those tuned-primary, tuned-secondary transformers used
interstage in transmitters. Aren't they just bandpass
filters? Apparently not.

But what really set me off was those two physics
papers. Their existence indicates that many others
besides myself have the same hole in our conceptual
structures. If people recoil in revulsion at the idea
that atoms might be like small resonant antennas,
something is seriously wrong!

If the "energy sucking" thread had fallen flat, then
I'd know it was I alone who never encountered
this bit of RF theory. Instead, it is clear that at least
a certain percentage of other knowledgable people
have similar problems. (Strange to get private
messages from people who say "I've been telling
this to colleagues for years, but they didn't believe
it.") (And very funny to watch a person saying that
such things violate physics and nobody should
discuss them, and in the same breath saying that

they are well-known phenomena, and therefor
nobody should discuss them!)

> The explanation by superposition and interference may be new

Not new, since the classical-EM explanation of the
waves around a small absorber assumes that the
absorber emits its own wavetrain, which creates the
interference pattern found around small absorbers.

What MIGHT be new (and obviously is new to at
least some people,) is the idea that if an absorber
could for some reason create a much stronger
local field (and emit a much stronger wave,)
then it would absorb far more EM energy. A
passive resonator obviously does this, but there
conceivably could be applications where an
active circuit would benefit from doing it
intentionally.

>('Basic research is what I do when I don't know what I am
> doing.' - Werner von Braun) What is not so acceptable is people (not
> William Beaty) persistently trying to ram their unfinished or easily
> disproved ideas into unwilling ears, and screaming 'suppression' when
> they can't publish at someone else's expense.

Apparently those here leaped to the conclusion that
I was doing this. (I was even accused of
hollering "suppression!!")

Could be a straw-man debating tactic, but I think it's
more. It's *exaclty* like bigotry: "these crackpots
are all the same, so we don't even have to read what
their disgusting little messages say." Then leap to
the attack without thought or without pause. They
don't hate *me*, they hate "those crackpots."

After following crackpots for about 15 years, the
only "suppression" I've ever seen is that nobody
pays attention to them. But in science, ever it
was thus, and not just for crackpots. Certainly
many mainstream theories have been "suppressed"
in similar ways until they were eventually
accepted. New ideas are frequently fought
tooth and claw before winning adherents. Planck's
Law was coined to describe this: new ideas don't
triumph by convincing their opponents, instead
the older scientists die and are replaced
by younger ones who grew up familiar with the
new idea. If LEGITIMATE ideas sometimes suffer
such treatment, imagine the barriers placed
before unorthodox ideas originated by independant

workers with no credentials. Whether or not
their ideas have merit or are supported by any
evidence, they have little chance of being
HEARD. Even their complaints are twisted
around and never actually HEARD. See:

They laughed at the Wright Brothers!
http://www.amasci.com/freenrg/arrhenus.html

When crackpots holler "suppression", I think
their real complaint is that nobody will even listen
to them long enough to hear their actual claims.
Their big mistake is to assume that they alone
are treated that way. Any close study of the
history of science reveals that this treatment is
common throughour science. Ever hear of the
"100 against Einstein" paper which was launched
as an attack against the new Relativity theory?

Today at least the supporters of unorthodox ideas
can create websites, and get them linked to the
"Crackpot portals" such as the ones listed at
http://www.amasci.com/weird/windex.html
There is even a peer-reviewed journal for
this sort of thing: JOURNAL OF SCIENTIFIC
EXPLORATION, http://www.jse.com

> achieved wireless power transmission.

Yep. A basic idea is to move those large plates
far away so the small plates then cannot couple to
them directly. Instead the small plates can only reach
out about 1/4 wavelength and intercept any EM
energy in the local region.

> Now, if you could figure out a way to turn the whole ionosphere into
> one electrode of a global capacitor.....

NOW you see a key idea. At ELF frequencies the
ionosphere IS basically a capacitor plate. In
particular,the earth/ionosphere waveguide is a
resonant cavity,and if driven at a higher harmonic,
many places on the earth will experience an intense
vertical e-field, just as if the ionosphere was one
conductor of a huge stripline transmission line.

Thunderstorms do "drive" this capacitor, but only
at DC. Even in clear weather, there is a significant
vertical e-field everywhere on the earth, since
thunderstorms charge the ionosphere positive
and the earth negative. The total energy in
the earth/ionosphere system is not that huge,

its something like tens of megawatts. If there
was a way to tap into it, it could only power a
medium-sized town.

A tall antenna can intercept a bit of the vertical leakage
"sky current," become charged to a high DC
voltage, and be used to run a simple
electrostatic motor such as those shown on
http://www.amasci.com/emotor/emotor.html

A physicist (at the U. of Indiana, I believe)
Dr. Oleg Jefimenko managed to get 1/16
horsepower from a variation of the Poggendorf
electrostatic motor (his was a spinning acrylic
cylinder surrounded with a "stator" array of
sharp knife-edges pointed inwards).
He powered his motor with a vertical wire
lifted by a small weather balloon. It's like a
"perpetual motion machine" that really
works. But since thunderstorms are
powered by the sun, then these electrostatic
"sky motors" are simply an exotic type of
solar energy device.

Build one what? A crystal radio? I suppose if I
measured the received power in a crystal radio with
and without a resonator as part of it, I could show
that the version with the resonator received far more
energy than the one without. I could even dip the
inductor in a gallon of LN2 to increase the Q, and
show that the received energy was even higher.
If I do this, will scientists everywhere come and
grovel at my feet?

:)

Or perhaps you've misunderstood the nature of the
"energy-sucking antenna effect" I've been talking
about. It's certainly no perpetual motion machine.
I don't quite understand why folks here have such
a problem believing that this can work (especially
when others here have posted material from texts
on antenna theory which show that the idea is
nothing exotic.)

But seriously, a guy in Chicago mentioned that he's
built several little motors which run from resonators
tuned to local AM stations. If a fraction of a watt
is attainable from transmitters that aren't so very
far away, then a very efficient DC motor can be
spun using the irritating patter of AM disk jockies.
AM stations ARE good for something after all!

The transformer-type meter works by measuring current and voltage separately. It can indeed be thought of as a kind of directional coupler. The ARRL Antenna book and some editions of the Handbook have good explanations and some projects. Sadly, in recent years they've dropped the simplest version, which used a capacitive pickoff to measure voltage, in favor of one that uses an additional transformer.

The most common SWR meters that I've seen are variations on the following construction: A length of coax connects the input and output terminals. The outer conductor is connected at only one of the terminals. The coax passes through a toroid which has a winding on it. This serves as a transformer which produces a signal proportional to the current on the center conductor. There is no current in the outer conductor, and it serves only as an electrostatic shield to eliminate capacitive coupling to the transformer winding. A circuit is then attached to the center conductor to pick off the voltage. These two signals are fed to a bridge that outputs the sum and difference of them, which are then used to compute SWR, either digitally or by feeding to a calibrated meter. It is important to note that the sum and differences are done at RF, not DC, so the relative phases are preserved.

Here's the theory. It can be done without the complex number arithmetic, but it's much harder that way!

The general form of current and voltage in a lossless line of impedance Z0 at a distance z along the line and at time t is:

V = VF*exp(j*w*t - j*k*z) + VR*exp(j*w*t + j*k*z)
I = (VF/Z0)*exp(j*w*t - j*k*z) - (VR/Z0)*exp(j*w*t + j*k*z)

Here w (usually an omega in the textbooks) is equal to 2*pi*f where f is the frequency, and k is 2*pi/wavelength. j is the imaginary unit, and exp is the exponential function. VF and VR are the forward and reverse voltages. They are complex numbers. In other words, each has an amplitude and a phase.

This equation tells you just about everything you need to know about transmission lines. You can derive the Smith chart from it if you like.

To examine SWR, assume that the meter is at z = 0. There is nothing special about this point. To measure at a different point would just change the phases of VF and VR in such a way that the SWR would be the same, but z=0 makes the math simpler. Having set z = 0, note that everything is multiplied by exp(j*w*t). We can drop this common factor from the rest of the calculations.

The equations now read

V = VF + VR
I = (VF - VR)/Z0

Signals proportional to V and I are produced as described above. The bridge circuit then produces the sum and difference quantities

VF = (V + Z0*I)/2 and VR = (V - Z0*I)/2

SWR is defined as (|VF| + |VR|)/(|VF| - |VR|). The remainder of the problem is how to come up with this quantity. Three common ways are

1. A meter where you first read |VF| to set the forward power to a "set" mark, then flip a switch to read |VR| on a scale calibrated for SWR. These are hard to use because you constantly reset the forward power. This is very tedious to do while adjusting an antenna tuner.

2. A cross-needle meter. |VF| goes to one needle and |VR| to the other. Scales are calibrated as PF and PR, and lines of constant SWR are drawn which can be read at the crossing point of the needles. These are much better than #1 but it's still a bit hard to focus on the crossing point of the needles. Your eye is drawn to whichever needle is moving more.

3. The best is a computing SWR meter. Analog or digital circuits are arranged to perform the sums, differences, and divisions, and results are displayed as you please on an analog or digital display. My preference is the kind that uses two analog meters, one reading net power (PF - PR) and one reading SWR. These are the two quantities you really care about.

Special consideration must be taken at QRP to avoid errors due to diode drops. Germanium diodes are often used because of their low voltage drops, and op-amp circuits that linearize diode response have been used. There may be other techniques.

From: George Spear AA1PD <aa1pd@yahoo.com>
Message-ID: <8bm7dpaev1@nnrp1.deja.com>
Source record: 62039

I plan to get going with QRP Mobile CW using about 4 watts into a Ham stick. I am usually in the car between 9-5 and want to have some qrp fun as I drive around visiting hospitals (I am a sales engineer for a software company) I have been assuming that I want to use my 20M rig but I read a post recently here where a backpacker was advised that contacts would be easier during the day on 40 rather than 20. It was not clear why the guy posting felt this was so but it has me wondering if 20 or 40 would be the better daytime band. Any recommendations would be appreciated.

Thanks! :-)

2537. probes for used oscilloscope

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-26 00:00:00 UTC
From: niebur@russell.mb.jhu.edu
Message-ID: <m2pushgsfj.fsf@russell.mb.jhu.edu>

So, I picked up dual trace oscilloscope, a HP-1222A, at the Baltimore Hamfest. The price was very reasonable but it came without probes. It seems to be working alright; at least when I stick a paperclip in the connector I get a beautiful (distorted) 60Hz trace. So, I need to buy a probe. Four questions:

1) I suppose I need to buy _two_ probes in order to be able to use both channels simultaneously, right?

2) I won't need a third probe for the ext. trigger; just a piece of coax with a BNC connector and two pieces of wire at the other end would work for that, right?

3) Where is a good place to buy scope probes? The vendor at the hamfest recommended probemaster but they don't list the HP-1222A.

4) Should there be more than one probe available that works with this model, what should I pay attention to?

Sorry to bother the group with these questions but, of course, the scope came without manual and I could not find anything on the net (there is an oscilloscope-FAQ but it seems to be off-line, and HP does not even list the model any more on their www site).

Thanks for your information!

Hi All,
I need a relay RL1 for the SB-401. It is the 5-pole DT relay, Heathkit part #69-40. Used or surplus is OK.

Can anyone help?

Thanks,

I've had the opposite experience, and have found 40 meters great for daytime QRP. But it's been on CW. On 40 meters during the day, you'll hear stations from a radius of around 600 - 700 miles and under. Signals are a bit weak, but steady. I find signal levels to be fine for CW QRP, but they might be marginal for SSB. Also, a vertical antenna is a poor choice for this range. A horizontal antenna up between 1/4 and 1/2 wavelength is much better. So for SSB mobile operation, daytime 40 is probably not the best choice. It's fine for fixed CW operation, though, unless you live where there are very few stations within a few hundred miles.

Yes.

> 2) I won't need a third probe for the ext. trigger; just a piece of
> coax with a BNC connector and two pieces of wire at the other end
> would work for that, right?

It depends on what you want to trigger from. If you'll always have a low-impedance source for the trigger, a piece of coax will be fine. But at 30 pF/foot (100 pF/m), even a fairly short piece can present a very low impedance at even moderate frequencies. So if circuit loading is a problem you'll need to use a probe for the external channel too. Of course, you can borrow one from one of the other channels if you want to watch just one channel while externally triggering.

> 3) Where is a good place to buy scope probes? The vendor at the
> hamfest recommended probemaster but they don't list the HP-1222A.

I don't have experience with low cost probes, but others have recommended a vendor.

> 4) Should there be more than one probe available that works with this model,
> what should I pay attention to?

For most purposes, 10x probes are better because they have a higher impedance and therefore load the circuit less. 1x probes are seldom necessary unless you have to deal with very small signals.

A 10x probe has to be able to accommodate the input capacitance (and resistance) of your scope input. An input resistance of 1M ohm is standard, but the capacitance is different for different scopes. So you need to make sure that the probe can be adjusted properly when connected to your scope. Tektronix scopes have the capacitance printed right at the input connector; I don't know about HP scopes.

Cheap probes are almost always a bad idea if you need really good signal fidelity. Getting very good fidelity is difficult to do, and lots of

cheap probes do a poor job. They're fine, though, for casual use, and
can be a lot cheaper than a genuine Tek or HP probe.

Ernst, the things you need to look for in a probe are:
1. Will it work into the input impedance of the oscilloscope
2. How long is the cable
3. Does it attenuate 10:1 or 1:1 or both, some even have 100:1
4. What bandwidth is of concern
5. Does the probe output connector fit the oscilloscope

You can buy probes a lot of places. The place I bought mine was Electronc Xpress or something like that. Good prices, decent selection. They have a web page and a catalog. Probes run around $15 each unless you get the ones from the 'scope company for a lot more.

The Earth is a conductor. Wouldn't matter much if it wasn't. The capacitance between the surface of the Earth and the remainder of the universe is 707 microfarads. Why argue about it ? I've got much bigger capacitors in the power unit of this computer I am messing about with.

Capacitance is in direct proportion to the diameter of the heavenly bodies. So our Sun has a somewhat greater capacitance than ours.

But just consider the capacitance of the spiral nebulae in Andromeda to the rest of the universe. Now that IS big ! And it's not an electrolytic type either.

Stop worrying. Take an aspirin. Have a good night's sleep.

> filters? Apparently not.
>

Expand your definition of impedance matching to include the context.
Impedance matching is not always performed to obtain maximum power
at the matching point that you think is or would typically be thought
of as the matching point. (amplifiers and speakers are a notable
example, where optimal and uniform power transfer to the environment
is constrained by the way speakers work which in turn requires a
suitable impedance transformation so that the amplifier supplies
a constant volatge across the audio spectrum rather than constant
power to compensate for the characteristics of the loudspeaker).

Ultimately, the purpose of a filter is to remove parts of the signal
so "filter" is synonymous with "frequency dependent power attenuator"
which is synonymous with "frequency dependent impedance mismatch".

Instead of thinking of a high pass filter as it is usually presented,
in terms of what you build and restrictions on the load you expect,
you can look at a high pass filter:

```
-----||-----+-...-+
C | |
/ /
R \ \ R_Load
/ /
| |
```

as a frequency dependent impedance mismatch to a current divider.
The impedance of the divider is R || R_Load. The impedance of the
capacitor is 1/jwC. The maximum power is transferred when the
impedances match:

1/jwC = (R || R_Load).

for optimal solutions with fixed w and C. Implicit in the assumption
that the gain is v_out/v_in, is the restriction that you intend it
to be a voltage source so that R >> R_Load or equivalently,
(R || R_Load =~ R, leaving you with the usual:

1/jwC = R ---> |1/wC| = R , or in terms of w, w = 1/RC.

> that atoms might be like small resonant antennas,
> something is seriously wrong!
>

How about small resonant antennas act like clusters of atoms
because that's what antennas are made from? Start with the
appropriate scale for the fundamental process and interpret
it in terms of the familiar instead of starting defining the
fundamental process as what you think it should be because
it's familiar and then trying to force the real process at
a vastly different scale to behave as you expect.

> discuss them, and in the same breath saying that
> they are well-known phenomena, and therefor
> nobody should discuss them!)
>

If the person is a physicist, perhaps it's because their
collegues are polite.

> conceivably could be applications where an
> active circuit would benefit from doing it
> intentionally.
>

This picture is due to the fact that you want atoms to behave
like antennas rather than antennas to behave like groups of
atoms, which an antenna obviously is. Due to the asymmetry
in 1 atom and a lot of atoms, and the scale involved, the
two are not equivalent and determining the behaviour of an atom
by adding phenomenological parameters to groups of atoms (
an antenna) or explaining atoms in terms of groups of antennas
(groups of groups of atoms) is both convoluted and self-referential.

> After following crackpots for about 15 years, the
> only "suppression" I've ever seen is that nobody
> pays attention to them. But in science, ever it

No. That isn't true. You need only look at the billions of
dollars spent on star wars weapons systems. Or how about the
psychics and tarot card readers? Or the people suckered into
dishing out money to support a crock, whether deliberate or
the result of delusion on the part of the so-called researcher
that has no understanding that outliers aren't typically
indicative of new phenomena and at best indicate the experiments
need to be done over, by other people and with some assuracne that
other experiments have different sources of systematic error.

So, the promotion of complete bullshit disguised as science
cost me and everyone else that pays taxes money everytime
some idiot politician likes the results better than reality.
If people WANT to pay for bullshit, fine. Put bullshit in
the bufget and vote.

> Law was coined to describe this: new ideas don't
> triumph by convincing their opponents, instead
> the older scientists die and are replaced
> by younger ones who grew up familiar with the

That's a tired cliche. The people most unhappy with
quantum mechanics did the most to advance it because
they didnt like ad hoc rules and inconsistency.
Dirac really wanted the proton to be the other
solution of the equation that bears his name, but
you didn't see him clling to the idea when it was
obviosly not. Fringe science relies on ad hoc-ery
and jargon.

What I've seen in this newsgroup from the proponents
of "new science" is a REFUSAL to apply current
science, like quantum mechanics to anything except
in a way that makes it just like classical mechanics
except with a new name. That assertion you made
is crap. Most fringe science represents their so-called
science as the only advancement since maxwell or whomever
that happens to be dead for more than 100 years.

Not 1 person have I seen attempt to produce anyrhing
new or unconventional that goes beyond what is known,
only what was known 150 years ago. Since I already
have the benefit of thousands of scientists over that
150 years to check things out some, I'm hard pressed
to accept claims of "einstein got it wrong".

> before unorthodox ideas originated by independant
> workers with no credentials. Whether or not
> their ideas have merit or are supported by any

That's true in any endeavor, but at least it's not as bad in
science. Medicine and business are far more intolerant. I'm
afraid you cant improve human behaviour that has nothing
to do with science by making all opinions equal. Going
upstream against the establishment is a fact of life.

> evidence, they have little chance of being
> HEARD. Even their complaints are twisted
> around and never actually HEARD. See:
>
In that case, you should be involved in the current issues
such as the dvd cases and digital millenium copyright act
suits which will determine just how much legal right

you have to be heard, since they seek to control information.
I know of no scientists that want the job of controlling
information to earn a paycheck.

> Today at least the supporters of unorthodox ideas
> can create websites, and get them linked to the
> "Crackpot portals" such as the ones listed at
> http://www.amasci.com/weird/windex.html

At least for now. Should the current lawsuits succeed,
your ability to do so is likely to be curtailed at the
whim of someone with a conflicting interest and the
money to pay for it to prevail.

Try Tucker for scope probes. You will probably have to pay $20
to $50 for a set. Hope that doesn't exceed the cost of the scope.The scope
probes have some tricky ways to minimise
their input capacitance and thus don't load the signal. Most applications
don't need them.
Also, get yourself some coax. Put BNC connectors on one end and
separate the braid and the center conductor on the other end and
put alligator clips on. You can use that for the sync line and other
purposes.

Old scopes are really handy and econonomical, until they die.
Then you can keep them for parts of toss them out and shop for
another.

Yes , I know what you say is correct.I only meant that this was a useful view
of the device. I guess I could have found a better way to say it. The fact that
it does not show a 50 ohm resistive load as a match to a 50 ohm reactive load
is all the better. I am not so certain that it will appear as an infinite SWR
regardless of the distance from the meter to the load(keeping this distance
limited to a couple of wavelengths) This is something I have never tried.

Yes, it's well-known in *field theory*, but I meant that it is not so
well-known in the context of tuned antennas.

The 'passive amplifier' is a practical demonstration of the effect. It's
not really an amplifier, of course: it's a field concentrator and your
explanations fit it quite well. Anyone can make one. You need a
cardboard box, about 30 cm cube but it's not critical. Also, a bit more
difficult, is an air-spaced tuning cap out of an old radio. A plastic
film one out of a newer radio will work but is not as good.

You wind 50 to 100 turns of thick (1 mm^2, say) insulated wire around
the box to make a coil (inductor) and connect the cap across it. Stand a
portable radio with a ferrite antenna next to the open end of the coil
(the axes of the coil and ferrite rod should be parallel, if possible
collinear), not too near, and tune the radio to a weak station near the
middle of the AM band (MF or MW in Europe). Now try to tune the coil
with the tuning cap. If you have roughly the right number of turns on
the coil, it will tune up and the sound from the weak station will
increase strongly. If the radio is too close to the coil, there will be
a dip in sound level when the coil is exactly on-tune. If this happens,
move the radio away a bit.

>Yep. A basic idea is to move those large plates
>far away so the small plates then cannot couple to
>them directly. Instead the small plates can only reach
>out about 1/4 wavelength and intercept any EM
>energy in the local region.

Sorry. The small plates are ALWAYS coupled in exactly the
same way - by the capcitance. The only way the separation
can make the coupling unimportant, in which case that means
you can take them to be at infinity with no loss of generality.
In other words they cant contribute to the result in any
way and might as well be removed altogether.

>resonant cavity,and if driven at a higher harmonic,
>many places on the earth will experience an intense
>vertical e-field, just as if the ionosphere was one
>conductor of a huge stripline transmission line.

Which is just given by the electric field you get from the charge
you induce spread over 4*pi*(6300 km)^2. That's just the potential
difference you can maintain over the entire area divided by the
earth to ionosphere capacitance. I have no idea what "driving
with a higher harmonic" is going to add to this problem. Just
from energy conservation alone, figure the input energy required
for a trivial 100 V/m (by comparison, this is approximately the
E field between the two edges of a 9Volt battery along the perp-
endicular line connecting them - 5V between 2 traces on a pc board
separated by 10 mils is 125,000 V/m along the common perpendicular).

>and the earth negative. The total energy in
>the earth/ionosphere system is not that huge,
>its something like tens of megawatts. If there
>was a way to tap into it, it could only power a
>medium-sized town.
>

The only reason the potential difference can exist is if it
reflects an equilibrium condition. Otherwise, energy flows
until it happens. Work is required to acheive a non-equilibrium
condition. The only meaningful way to discuss that energy you
want to tap is to know what the energy is referenced to.
(you cant extract the energy stored between the plates of a

capacitor without placing something inside that can change
the electric field at no energy cost. The only way to "tap into
it" implies perpetual motion.

>He powered his motor with a vertical wire
>lifted by a small weather balloon. It's like a
>"perpetual motion machine" that really
>works. But since thunderstorms are
>powered by the sun, then these electrostatic
>"sky motors" are simply an exotic type of
>solar energy device.
>
But, you forgot that you have to supply the lift to place the
wire there. This isn't an insignifcant point because the same
energy that separates the charges that give rise to a potential
difference, must be overcome to keep the wire there. Since the
sunlight that heats the atmosphere and gravity determines that
distance and any mechanism your balloon uses to lift the wire
will eventually equilabrate, the wire will fall, regardless of
it's mass. Current flow means draing charge, therefore the
forces that position the ionosphere at a fixed height would
change. The most you could do is to try and take advantage
of the fluctuations about the stored energy, not the absolute
value of the total. If you want a better way to become frustrated,
try maxwell's demon or szilard engines as an example of just
how non-obvious the gotchas can be.

One thing it is possible to do is compute for free. The energy cost
is in erasure. The erasure can be the exact reversal of the computation
and in that case, the two are equal and you end up with no net loss.
It also appears you cant get the result of the computation either.

>
I'm afraid that went over my head. If a group of people
were attempting to contrive a way to save old physics
because they didn't understand anything done in the previous
150 years, yes. In fact, that very thing is typical. The
pseudoscience done by pseudoscientists today is exactly
like someone 150 fifty years ago insisting that copernicus,
kepler, galileo and the rest were wrong and then going off
to rebuild everything with epicycles and retrograde orbits.
Then upon becoming confused, due to the sheer convoluted
model they've created and the inability to keep adding
epicycles to maintain the model, start predicting phenomena
that have already been disproven by observation with explanations
that match the observation. Finally, they claim th suprression
of epicycle physics by closed minded copernicans, hundreds
of years after copernicus.

>But we'll never know, will we?

Yeah, we will. If someone 150 years ago deccided to resurect the
ptolmaeic view of the universe and claim copernicus was mistaken,
I'm afraid I would have to say the same thing about them that I
say about the current crop of the misinformed, now.

2555. Re: Help: with QRP mobile 20M or 40M?

Newsgroup: rec.radio.amateur.homebrew

Thanks for your comments Roy. I only operate CW when on HF and will be using a key strapped to my leg. I am going to read into your comments about weak signals not wanting to use a vertical etc. that for mobile CW QRP 20M would be the better band. I just had a contact yesterday from home with a fellow who had just built a 330mW Gsprat TX. We QSO'd for 30 minutes with no problems except chasing him as he drifted. I am in maine and he was in NJ. But I was using a windom at 50 feet.

2556. Re: How does an SWR-Meter work?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-27 00:00:00 UTC
From: Reg Edwards <G4fgq.Regp@btinternet.com>
Message-ID: <8bnmmllnp1@plutonium.btinternet.com>
Source record: 61961

With a purely reactive line termination the power absorbed by the load must be zero. So the magnitude of the reflection coefficient must be unity with a phase angle of +/- 90 degrees.

The SWR is a function only of the magnitude of the reflection coefficient. The phase angle of the reflection coefficient only shifts the locations of the voltage peaks and troughs up or down the line relative to the location of the reflection.

SWR = (1 + RC) / (1 - RC).

So at the point of reflection the SWR is infinity.

If the so-called SWR meter does not indicate infinity then it must be due to imperfections in the mter.

2558. Source of very flexible coax cable?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-27 00:00:00 UTC
From: Mark Nelson <mnelson@pedinc.com>
Message-ID: <38DF818D.9FFF0324@pedinc.com>
Source record: 61963

In designing a body-worn radio for a marathon runner, I need some VERY flexible (and small, of course) coax to connect the transceiver (on the waist) to a shoulder-mounted antenna. RG-174 in most of the forms familiar to me is too stiff, and would chafe the runner. Since the distance from radio to antenna isn't very long, I'm not worried about losses much (even at 900 MHz). WR Gore quoted me $500+ per assembly for their .047" coax with connectors -- I'm looking into the surplus bins at Hamfests as more appropriate to my budget. The radio will use a SMA connector.

Can anyone point me to a source (new or surplus)?

Thanks,

William, I think folks think that you think that
you could get as much energy as you wanted by
connecting up more and more of these resonant
antennas.

Suppose you had two of these antennas that were
widely separated and each was receiving power
equal to P. Then suppsoe you brought them together.
The total power would be reduced to less than 2P
and finally becoming P as the antennas became
coincident.

Do you agree with that?

Opinions expressed herein are my own and may not represent those of my employer.

Just a followup for those who may be curious. The resistors I have are pretty much as described above. I wired one with short heavy copper wire to a BNC connector, and hooked this up (via a pl-259 to BNC adapter) to my MFJ 259 SWR analyzer.

SWR was flat at two-to-one from the bottom end of the analyzers range (around 2 MHz, I think) up to about 15 MHz, at which point it... wasn't flat anymore. :-(

Thanks to everyone for all your input!

best regards,

Then it's typical "newsgroup mindreading." I
think that they think that I think that they
think that I mean "XX" when I really wrote "YY".
Or something like that.

I think.

The cure is to READ messages, and not to assume
that they mean anything else than they state.

> Suppose you had two of these antennas that were
> widely separated and each was receiving power
> equal to P. Then suppsoe you brought them together.
> The total power would be reduced to less than 2P
> and finally becoming P as the antennas became

>
> Do you agree with that?

Certainly! If two resonant antennas were within
each others' nearfield region, then they would no
longer act as separate devices, and only a single
"antenna" would exist. The only energy available
for reception is the energy emitted by the distant
transmitter.

Things are still weird here. If one person insists
that small resonant antennas violate physical law,
and others insist that antenna textbooks describe
this type of antenna and always have... doesn't it
mean that the people objecting to the existence of
small resonant antennas are WRONG?

As a publicly-declared crackpot, I need not cover up my weird assertions to slip them under people's defenses. If I was talking about "perpetual motion machines", then I would SAY the words "perpetual motion". Over and over, so there would be no mistake.

It sounds like the main problem here is hatred. If I am a disgusting pseudoscientist, then nobody can trust a word that I say, and if I say "energy-sucking is a part of conventional physics", people either ignore it, or for some reason they imagine that I'm REALLY saying something about perpetual motion machines. Under these conditions, understanding is clouded by hatred, and discussion becomes impossible.

I could say "Ohm's law is very useful", and sundry people would attack, and try to prove that Ohm's law violates physical law. It's ridiculous.

And do you also agree that there is an upper
limit as to how much energy a small resonant
antenna with lossless components can pull

out of a given incident em field from a
far away transmitter.

Opinions expressed herein are my own and may not represent those of my employer.

You believe I'm talking theory here, not experiment?
You assume that Dr. Jefimenko's "sky-powered" motors
were a hoax or something? You're in for a suprise.

The net electrical output of thunderstorms across the
globe creates a continuing vertical current,
causing the ionosphere to be positively charged with
respect to ground. One thing you possibly aren't
considering: an equal current must flow downwards
everywhere else on Earth, otherwise the potential
at the ionosphere would be rising continuously. In
other words, thunderstorms act like DC generators,
and the earth's atmosphere acts as a resistor, not
an insulator. IIRC, the earth/ionosphere capacitor
will discharge within a few minutes if all
thunderstorms worldwide were to turn off their
charge pumps simultaneously. Earth's atmosphere
is a fairly leaky "dielectric."

> (you cant extract the energy stored between the plates of a
> capacitor without placing something inside that can change
> the electric field at no energy cost. The only way to "tap into
> it" implies perpetual motion.

No, it's just that you aren't considering the small
"leakage current" that accompanies the 100V/meter
vertical e-field. If the vertical current in the
atmosphere was zero, then you're right, there would
be no good way of extracting energy from the earth/
ionosphere capacitor, short of sending up a 50-mile

wire to make contact with the upper "plate." Since
the atmosphere contains ions caused by cosmic rays,
it behaves as a leaky insulator.

>
> >He powered his motor with a vertical wire
> >lifted by a small weather balloon. It's like a
> >"perpetual motion machine" that really

> >powered by the sun, then these electrostatic
> >"sky motors" are simply an exotic type of
> >solar energy device.
> >
> But, you forgot that you have to supply the lift to place the
> wire there.

You misunderstand. Jefimenko's electrostatic
motors ran continuously. Once aloft, the vertical
wire became charged through conductive contact with
the atmosphere, and not just through electrostatic
induction. The motor extracted a continuous flow of
charge from the "antenna," which flowed through the
motor and into ground. It did not simply run for a
brief time as the balloon lifted the wire. These sky-
powered motors are well-known to atmospheric
physicists, and date back to the time of Franklin's
work in electrostatics. There's nothing crackpot about
them. Unless you consider colonial printshop owners who
fly kites in thunderstorms to be vile crackpots who
will destroy science as we (knew) it.

The vertical current is possible because the atmosphere
is a conductor of the ionic type. The 100V/m vertical
e-field drives a weak vertical ion flow. Any tall
metallic structure will intercept a part of this current,
and if that structure is insulated from contact with the
ground, a small electrical load can be connected to it.
Things can be improved by attaching sharp metal points
to the top of the structure, in order to generate corona
discharge which provides more ions and locally reduces
the atmospheric conductivity above the metal structure.

Since Dr. Jefimenko claimed to have measured up to
1/16 HP, the output of his "DC antenna" might have
been a few hundred microamps at a few kilovolts.

For the overly-enthusiastic people who want to tap
into this energy source, they should become aware that
the total power in the system is less than that of
a big coal-fired plant. "Sky powered" devices might
be fun toys, but you can't run the country using
this energy source.

> If you want a better way to become frustrated,
> try maxwell's demon or szilard engines as an example of just
> how non-obvious the gotchas can be.

Or, if you confront an actual electrostatic motor
which is actually running continuously while
connected to a long vertical wire, it means that your
understanding of the physics behind it has a major
hole somewhere.

2572. Re: How does an SWR-Meter work?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-27 00:00:00 UTC
From: Tom Bruhns <tom_bruhns@agilent.com>
Message-ID: <38DFCF9B.46F9DB64@agilent.com>
Source record: 61977

If you look on deja news, you should find good explanations in the homebrew and/or the antenna groups.

A quick answer: they sample the current and the voltage at a point on the line. The samples retain phase information. They effectively ratio the two, and the ratio chosen is impedance (resistance) for which the meter is calibrated. For example, in 50 ohm line, the ratio of voltage to current when there's only "forward" power will be 50 volts/amp = 50 ohms. If there's only "reverse" power, the ratio (because the current will be in the opposite direction for a given voltage polarity) will be -50. The measured difference from the calibration ratio will tell you the apparent amount of power in the "opposite" direction. You'll find much more detail in the old postings...I've made a few, and others have as well.

Some may argue that it's not really an SWR meter. But that's the name we've given it, and as far as I'm concerned, it's useful for telling me the SWR on a line whose impedance is nominally the same as the meter's calibration impedance. Saying it's not really an SWR meter is, to me, like saying the speedometer in a car is really not a speedometer: it can be miscalibrated, and you might use it to measure the speed when the car is up on blocks with the wheels spinning. If you misapply it, it will give you wrong answers. That shouldn't be news. And some of it comes back to just what you accept as "SWR" on a line: does the line have to be long enough that you actually have at least one voltage node and at least one voltage antinode? Or can you accept a generalized definition that allows SWR to be defined in terms of forward and reflected power as measured at a single point? I happen to accept the generalized defintion.

Cheers,
Tom

2576. Re: Help: with QRP mobile 20M or 40M?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-27 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <38DFE629.D370D8A@eznec.com>
Source record: 61981

I tend to avoid 20 meters for QRP operation because it seems that nearly everyone on the band is wanting to work DX and it's sometimes hard to get a domestic station to ragchew. (On the other hand, if you can't fix it, feature it. It's fun, and easy, to work DX with QRP on 20.) The QRM level can get pretty high, too. But there's no doubt that daytime signals are strong and your signal will be very readable by lots of other stations (if QRM isn't too bad). And I'll defer to people who have done more QRP operating on 20 meters than I have.

Besides the fact that a vertical is more appropriate for the elevation angles you need on 20 than for daytime 40, a 20 meter mobile vertical will also be more efficient than a 40 meter one. So all and all, if I were you I think I'd go for 20. But 40 wouldn't be a totally lost cause either.

One of my more memorable QSOs was back when 10 watts input was generally considered QRP. I designed a rig to be as efficient as I could make it, and it put out about 8-1/2 watts with 10 watts input. With this rig and a CB whip antenna (base loaded with a powdered-iron toroid core coil and bumper mounted on a VW squareback), I worked JA on 40 meter CW while driving down US Highway 101 on the Oregon coast. Fun. (Of course, this wasn't daytime -- it was 1:00 or 2:00 in the morning.)

This is one of several reasons I chuckle when I hear testimonials about great DX QSOs as being proof that a particular antenna is great. I assure you, the antenna I was using really sucked. But it was good enough.

Just what is the point behind this so-called "energy sucking" nonsense? There doesn't seem to be unusual behavior described here at all. The examples given here and on the website illustrate nothing more than basic principles of impedance matching, and their use in maximizing power transfer.

> I don't quite understand why folks here have such

> nothing exotic.)

Just HOW exactly is it supposed to work? The claims you are making are rather vague. Exactly HOW MUCH power do you claim a small, lossless, resonant antenna can extract from a given propagating EM wave? (compared to say, the power available from a half-wave dipole.)

hehe - funny how we all have different experiences.

I've never had much luck on 40 - noise level mostly too frustrating, especially during the day and especially at this point in the sunspot cycle.

Also, when you said QRP, I sort of assumed CW. Seems like all the phone stations on 20 are running a kilowatt, so 20 phone is generally not the place a QRPer wants to be.

But, I do find CW mobile a bit of a challenge unless I have someone in the car to take notes, or unless I already know the other party so the name, call, etc. is already etched into the brain. Roy's memorable QSO reminded me of one of my favorites, which absolutely runs against what I just said!

Anyway, a couple of my teams are about 120 miles away, and I generally try to pack the rig when I go down to visit them. One trip last year I was coming home late in the afternoon and was listening around the phone band when I heard a PA3 calling CQ. Well, I gave him a yell with my mighty 3 watts into the Hamstick and to my surprise, he came right back. We had quite a nice chat across the pond - he gave me a 56 which was probably generous. It sure shortened the drive home :-))

THat was probably my last SSB mobile contact - as much fun as it was, I really dislike phone! From the mobile, my 40 meter attempts are more often than not the QRP-L fox, which is a challenge from the fixed station, so my dislike of 40m mobile may be a tad prejudiced. But while I have often had a hard time coming up with a Q on 40, I've never had a problem on 20. Obviously, Roy and I are just different! I'm sure you're different too, and will find your experiences different than either of ours.

A distraacted Science Hobbyist made these comments concerning
>Re: DOH! My big "energy sucking" error!:
>
> The cure is to READ messages, and not to assume
> that they mean anything else than they state.

Yes, it is. I've addressed every facet of your antenna with
halliday & resnick level physics, and so far, no one, yourself
included, has pointed out an error or inconsistency in what
I've posted. In fact, most of the other posts are consistent
with what I've posted. Your concept of "loosely coupled",
but not by anything that matters or has any properties like
capacitance lacks a certain physical basis and is not needed
anyway.

>
> Certainly! If two resonant antennas were within
> each others' nearfield region, then they would no
> longer act as separate devices, and only a single
> "antenna" would exist. The only energy available
> for reception is the energy emitted by the distant
> transmitter.
>
So, would you like to provide a qualitative description of the
process that doesn't involve the effect of the capacitance in
altering the efficiency and why the addition "professorial
knucklewraps" of the "size" and "energy sucking" song and
dance fix this?

> Things are still weird here. If one person insists
> that small resonant antennas violate physical law,

No one claims a resonant antenna violates any known
physical law. It's only your concept of what a resonant
antenna has to be and how you think it works that
violates any physical laws.

> and others insist that antenna textbooks describe
> this type of antenna and always have... doesn't it
> mean that the people objecting to the existence of
> small resonant antennas are WRONG?
>
It does if you take useful semantics that facilitate
engineering decisions by providing rules of thumb and
use those semantics as a basis for a fundamental

picture of the process. You'll have to call it the
Energy theory of the rules of thumb sucking.

> defenses. If I was talking about "perpetual motion
> machines", then I would SAY the words "perpetual
> motion". Over and over, so there would be no
> mistake.

Not if it's an inescapable consequnce of what you are suggesting.
Just because you don't realize it, doesn't necessarily mean you
have an option about perpetual motion. However, by this point,
I haven't the faintest idea which of the previous possible
variations on the theme constitutes the embodiment of the "
energy sucking antenna" or your idea of how it works. I can
safely say an antenna that works, doesn't violate physical law.
The same cannot be said for your explanation of how it works.
If an antenna works and your explanation gives physics the
short end of the stick, My objection have nothing to do with
the antenna.

> It sounds like the main problem here is hatred.
> If I am a disgusting pseudoscientist, then nobody
> can trust a word that I say, and if I say "energy-
> sucking is a part of conventional physics", people

No. The main problem is that you refuse to address any objections,
which I've made point-by-point just to make it simple and others
have made. Instead, you just keep asking for objections. I'm sorry,
but no matter how flawed an idea, how wrong a concept, there are only
a finite number of objections that are possible without repetition.
If your plan is to ignore objections until all possible objections
have been ignored and then claim you already dealt with the
now ineveitable repetition, buy a vowel

> either ignore it, or for some reason they imagine

It does if you take it out of context. Try explaining how
you get charge moving at a constant velocity by applying
an electric field, since a = qE/m, not v. Without the
help of statistical mechanics, it isn't obvious that
V= IR (J = \sigma E);

A distraacted Science Hobbyist made these comments concerning
>Re: DOH! My big "energy sucking" error!:

> You believe I'm talking theory here, not experiment?
> You assume that Dr. Jefimenko's "sky-powered" motors
> were a hoax or something? You're in for a suprise.
>
No. I just dont see the mystery. I'll bet you spend
more energy than you can get returned is all.

> charge from the "antenna," which flowed through the
> motor and into ground. It did not simply run for a
> brief time as the balloon lifted the wire. These sky-
> powered motors are well-known to atmospheric

So, as soon as it starts, you can wind up the wire and
go home? That's your claim? I sort of assumed the balloon
and wire had to remain connected to the motor with the
balloon remaining aloft.

> e-field drives a weak vertical ion flow. Any tall
> metallic structure will intercept a part of this current,
> and if that structure is insulated from contact with the
> ground, a small electrical load can be connected to it.

Now, what is the result if the charge decreased drastically
because the entire planet figured it was cheap energy?
Or hasnt it occured to you that there's no energy freebie?

> discharge which provides more ions and locally reduces
> the atmospheric conductivity above the metal structure.
>
I dont care what you do, the energy comes from somwhere
and like it or not, something has to provide the
energy to remove. Remove enough charge and you'll
find out where.

> Since Dr. Jefimenko claimed to have measured up to
> 1/16 HP, the output of his "DC antenna" might have
> been a few hundred microamps at a few kilovolts.
>
So what? A potential difference is just that. I dont
need a balloon to use a battery, but I'm not claiming
anything special about the battery and certainly just
because I didn't put the atoms together inside,

doesnt mean I have to remain ignorant of the energy
source. sheesh...

> be fun toys, but you can't run the country using
> this energy source.
>
Then why the hoopla? You just claimed earlier that
it was a great energy source to tap. If it's less
efficient than a coal plant, why did you spend
the entire post, except for this paragrapgh
disputing me. Did you expect to surprise me?
Now, why dont you explain why it's impractical,
so you can discover it's what I told you in the
post you just disputed. Do you use a markov
chain news reader that assembles posts from
word content in the entire group, or is deliberate
misunderstanding just a tool to try and wear down
the readers?

> Or, if you confront an actual electrostatic motor
> which is actually running continuously while
> connected to a long vertical wire, it means that your
> understanding of the physics behind it has a major
> hole somewhere.
>

I dont believe I've ever encountered someone that deliberately
misunderstaands at every opportunity just to insure no information
ever flows in. Is there some advantage to mis-stating what
someone tells you just so you aren't stuck arguing with yourself?

Wow, thanks guys, I think that I have enough to get me started here.
The loop ckt. submitted by "CA" is interesting, plus the amp. uses the
venerable MPF102, my speed! I wonder if this kind of continuous,
single-turn, amplified loop isn't what "Wellbrook" uses, or would it
possibly need to be a low-Q, center-tuned loop to attain the upper bands at
one meter diameter? Plus, I wonder why they, or someone else, didn't just
go for the convenience of the E-field probes instead of the cumbersome loop?
Thanks agn., Ed W.

Great summary, Tom. Funny, the speedometer analogy was the same one that occurred to me.

I agree with you that an SWR meter measures SWR -- some more accurately than others. If you want better, look into a network analyzer or a vector impedance meter. You'll be able to measure SWR with far greater accuracy than you can with ham equipment. But you won't find them for $100 or $200. They're more like $20,000 - $30,000 and up. And you can't transmit through them.

Tom's employer will be happy to sell a very nice one to you.

From: Larry Benko <benko@aztek-eng.com>
Message-ID: <38E0D9BD.6EF77EF1@aztek-eng.com>
Source record: 61907

I am planning on doing Field Day this year with my
Icom-756 transceiver running from some large deep
discharge 12V batteries that I have. In the process
of measuring power requirements etc. I have noticed
that the transceiver outputs 100w (to a dummy load)
only for input voltages greater than 12.9V. For
lower voltages the power progressively is reduced and
for voltages less than 11.0V it shuts off. Clearly
this is acceptable for a situation where batteries are
being charged but when running off the batteries only,
the transceiver does not allow for the batteries to be
discharged very far before shutting down.

Enough for the history. Has anyone ever seen a device to
take a battery feet and boost the voltage a few volts?
This device would need to function for current draws of 20A
and be able to disable itself if the battery was being
charged since the transceiver has a maximum input voltage
of 16V. Conceptually this device could be an isolated 0 to
3V 20A supply that could be placed in series with the actual
battery and thus would be a much smaller device.

Thank and 73,
Larry Benko, W0QE

It appears that there is something wrong with the transceiver. Check the specifications and it probably says that it will put out 100 Watts over the entire acceptable supply range.

You may have a defective internal regulator. How are you measuring the supply? If you are measuring at the battery there may be some drop to the transceiver.

I'd put the reduction drive on the main capacitor too.

But in some ways, which it goes on may depend on how the capacitors are intended to be used.

There was a time when a lot of receivers had two tuning capacitors, and two dials. One was main tuning, and the other was bandspread. You could tune with the main dial, but calibration was limited and it didn't take all that many turns of the knob to tune across the dial, and if it was a general coverage receiver and you were tuning the ham bands the problem was even more obvious. So instead, you'd tune the main dial to a certain point, and use the bandspread. Sometimes the bandspread dial had only a logging scale, and sometimes it was calibrated for the ham bands or even shortwave broadcast bands. If it was calibrated, you'd have to set the main dial to a specific point, but of course you could ingore the calibration and just tune the main dial to near where you wanted to tune.

But one could also have a situation where the main dial covers a smaller segment of the spectrum, such as a ham band, and the second capacitor is only fine tuning. The main tuning has to be relatively good, and the fact that it covers a small segment makes that easier. But the fine tuning is only there to make very small tuning adjustments, of a few KHz or so either way.

In the former, you'd want the reduction drive on the bandspread capacitor, though you'd probably also want something on the main capacitor.

In the latter case, the reduction would be on the main drive, and the fine tuning is really like additional reduction on the main tuning.

With a regen with plug in coils, one could set up things both ways, though the reduction drive would have to be on one capacitor, the main one. You

could have a set of coils that cover the full 2-30MHx spectrum, if that's what you want, but then have a second set of coils that have parallel capacitors that reduce the effect of the tuning capacitors and thus their tuning range.

One can also look for tuning capacitors with 2:1 reduction drives built in. I've seen quite a few of those in consumer am/fm radios, at least in more recent equipment that actually uses variables with air spacing rather than mylar. If you had something like that, it might give reconsideration to putting the reduction drive on the bandspread capacitor, if you were using the second capacitor for bandspread rather than fine tuning.

If one is using the second capacitor for fine tuning, one can limit it's range by putting a capacitor in series with it, to make it in effect a smaller variable.

Another trick for easy tuning is to use large knobs.

And I've seen people suggest plastic protractors as ready made logging scales.

Hi Carl,

I also have an Autek antenna analyser. It's a very nice and convenient instrument. I can confirm the measuring accuracy. Thanks very much for your trouble to make the tests and publish your findings.

But the Autek is not an in-line SWR measuring device.

The ordinary SWR meter at 30 MHz only tells you whether you are likely to blow up your PA or not. It also keeps the CB swwrrrr fraternity happy.

Have you noticed not a single manufacturer specifies the measuring accuracy of his ordinary SWR meters. They don't even bother to state the reference impedance. Why don't they ? Simple, they don't have even the foggiest idea !

But most amateurs take SWR meters as telling the Gospel truth. Not that it matters very much anyway.

I heard of this situation before, not just with ICOM's. The only fix I have heard of is to add cells, which near impossible to do, then regulate it down. I don't know if they are available but placing in series a 6V deep cycle battery then building a regulator to drop the voltage back down to a desired level (13.8V). Beware, the fully charged batteries could be as high as 22.5V. Between the voltage and the amount of power you will be dropping a linear regulator will be generating a lot of heat (9V X 20 A(peak) = 180W). Even a partiality discharged you could be dropping a 100W (5V X 20A (peak)). A switching regulator may be preferred.

A DC to DC inverter are generally not very efficient and high power versions are expensive. Also, although I could be wrong, all of the one I have seen are unregulated.

> (snip...)

Since the resistors were designed to be bolted to a heatsink - achieving
their rated dissipation may in fact require this - why not do so? You
can
buy really big heatsinks cheap, and they're far less mess than things
with
oil in them...

The socket is a SK2A type. It can be found with RF Parts at
www.rfparts.com/sockets.html
or with Svetlana at http://www.svetlana.com/docs/tubeframe.html
or at http://www.surplusales.com/Tubes-Sock-Acc/TubeSktsmain.html (much
cheaper)

It's an SWR/antenna analyzer something like the Autek Research unit:

http://www.mfjenterprises.com/analyzers/mfj259.html

The resistor was a 1% 100 Ohm unit, and the meter read 2:1, 100 ohms, up to about 15 MHz. My benchtop multimeter showed the resistance to be fractionally over 100 ohms, well within the 1% tolerance of the resistor's specification.

> Paul G
> in New Jersey
>

Paul,

This is a very common arrangement for general coverage type receivers.

The "bandset" is for gross tuning. The receiver might have a large overall coverage. A unit might cover, for example, 6 to 19 MHz, which is popular for receiving Short Wave Broadcasts. Within this range there are "bands" where certain types of broadcasts tend to be clustered. There are many, but as an example there is the 49 Meter Band (6.0 - 6.5 MHz), for Short Wave Broadcasts, 40 Meters (7.0 - 7.5 MHz), for Amateur communication and Short Wave Broadcasts, etc..

The "bandspread" is then for fine tuning. If you use your "bandset" control to select your band of interest, say 40 Meters, you can then use your "bandspread" control to "spread" out the "band" over the larger portion of the dial, than if you only had the "bandset" to work with.

Using this as a guide, the 100 pF capacitor will produce a change in capacitance larger than the 15 pF capacitor, for the same amount of movement. In other words, if you were to turn the shaft 10 degrees, the 100 pF capacitor may show a change of 15 pF, whereas the 15 pF capacitor might only show a change of 2 pF.

If you then relate this to your tuning circuit, a 15 pF change in capacitance will cause a greater change in frequency than a 2 pF change. Therefore, the 100 pF capacitor would be your "bandset", or gross tuning, and the 15 pF capacitor would be your "bandspead", or fine tuning.

The 100 pF capacitor would be "setting" your "band" of operation, and the 15 pF would be "spreading" the "band" over a large portion of it's dial.

In operation you might set your "bandspread" for maximum capacitance, which is with the plates fully meshed, and then adjust the "bandset" to the bottom of your band of interest. Then, rotating the "bandspread" capacitor will allow you to fine tune the band of interest, from the low end to the high end. You can also do it in the other direction. Setting your "bandspread" control for minimum capacitance and then useing the "bandset" to set the top of your band of interest, would accomplish the same thing.

If you were using this receiver with a transmitter, it might be better to set the "bandspread" control at mid-range. Then use the "bandset" to zero-beat your transmitting frequency. This would then allow you to fine tune the receiver above and below your operating frequency by just using the "bandspread" control.

As to which control gets the 5:1 reduction drive, well this has to do with resolution. The "bandspread" capacitor is small and will change capacitance at a rate much slower than the "bandset" capacitor, for the same amount of rotation. For 10 degrees of rotation the "bandset" capacitor might change 5 pf causing a 135 KHz shift in tuning. On the other hand, the "bandspread" capacitor might only change 0.75 pF causing a 20KHz shift in tuning.

You may think that this is tending to say that the reduction drive should be put on the "bandspread" capacitor, because you can then reduce the frequency shift by a factor of 5 for the same 10 degrees. This would then take the above shift of 20 KHz and reduce it to 4 KHz. A much smaller increment and a much finer tuning capability.

But, then you have to ask yourself if the resolution with which you can set the "bandset" capacitor is sufficient to allow you to set it within 4 KHz of the frequency of interest. In the above scenario, it would be very difficult to reliably adjust the "bandset" control to a particular 4 KHz segment. However, with the reduction drive on the "bandset" control the 135 KHz/10 degrees shift would be reduced to 27 KHz/10 degrees, making it relatively easy to adjust your "bandset" to whatever band you wish.

In summary, the 5:1 reduction drive belongs on the "bandset" capacitor (100 pF). You could also put one on the "bandspread" but there would be little gain. I would be better just to get a larger knob.

Martin

Hello, Mark--

I wonder whether anyone in the NG is familiar with flexible coax cable for
biomedical applications? I'm not, but that's the direction I'd look.

A served (i.e., spiral-wound) shield may offer better flexibility, but it
makes
for a very leaky RF cable.

The group at:
http://www.space.com/space/launches/cats_launch_000328.html

Is trying to measure the altitude of a Rocket using GPS.
Normal non aerospace GPS receivers have a hard time handeling high GPS doppler rates
such as produced in the rocket.

I have no involvement with them at all.
I'm just a geek that was wondering if this is the best approach.
How hard would it be to measure the rocket position with a transmitting beacon on the Rocket?

My idea...
Put a beacon on the Rocket that transmits a short UHF CW pulse every second or so.
The duty cycle would be low enough to reduce average power.
(It could send a morse ID every 10 min to be legal)

Place 4 or more ground stations to recieve this pulse.

Use GPS to syncronize the clocks at the ground stations.
How hard would it be to measure the ariival time of the pulse with enough accuracy
to measure vertical distance?

Realize that the transmit time of the pulse is unknown, so we have four times of reception
to solve for 4 unknowns.

Rocket X,Y,Z and Time of Tx.
We can postprocess the individual GPS Rx clock offsets to know the different RX clock offsets to better than 100nsec.

How hard would it be to measure the arrival time of 70cm or 23cm pulse to better than 1 usec?
This would give an aproximate range measurment of +/- 900 ft.

How would you build the simplest pulse transmitter to do this?

How would you build a receiver to recieve the pulses.....
(Remember that the rocket can go Mach 3.5 so the doppler is not insiginificant.)
I was thinking a DC Rx tied to a reasonable gain Yagi.
The operational environment is out in the Black rock desert, so it should not be a high intermod environment on UHF.

From: "a.p." <apight@pa.net>
Message-ID: <38E141D7.8BFFAC35@pa.net>
Source record: 61927

Hi,

I couldn't find any information on the net on the various pots in the htx-10. So, I tinkered a bit and found;

RV1 = S meter adjust (50uV on AM for S9 makes a very scotch meter for SSB)
RV9 = Po adjustment for SSB (32W max on whistle up peaks)
RV16 = Po adjustment for FM and AM (32W max on FM. I set mine to 25W)
RV4 = max mic gain (I set this one for >100% positive peaks without going beyond 100% negative peaks on AM.)
The power output meter adjust is the one that is aft and to starboard of RV1. (I neglected to record the pot number. . .next time I take the cover off I'll report the RV number)

Note: I wasn't looking for a means of putting this rig on other bands and am not interested in doing so.
Note 2: There are a number of other pots on the board (RV11, 12, one in the center) that I would like to know about. I didn't see anything change when I tweaked them. Help would be appreciated. Heck, a schematic would be appreciated. . .

Hi Groups:

I own a Ramsey QRP 30 meter CW rig and it's complement QRP AMP linear. I like the setup and
have made some nice CW contacts. With the rig alone I can get .4 W out. I decreased the value of the collector resistor in the driver circuit hoping to get a little more out of the transmitter. It worked and I got .5 Watts. But the 3053 final can't seem to keep up with the change.
Would anyone suggest multiple 2N3053's or another device capable of handling the power without producing so much heat?
I would like to find a replacement for the 2N3053 that would not heat up so much that the power drops. Is there a replacement that would handle more dissipation without so much heat? I did some looking and found a device with similar characteristics as the 3053 but with a higher power ratings. The 2N3553 looks somewhat similar. Anyone out there know of a replacement part with similar voltage/current/gain and hybrid parameters?
I forgot to mention the power output of the transmitter when attached to the QRP amp goes to 2 watts out the antenna! If I drive the QRP AMP to higher than this my AMP oscillates and goes into runaway. Talk about HOT transistors. But that is another subject..

Thanks and 73

Yeah, the two web references both look a whole lot more suitable for limited budget home construction than trying to do it with wide-band op amps. I would suggest putting back-to-back parallel diodes from each antenna terminal to ground, to protect against electrostatic discharges. ESD can degrade noisefigure of transistors without actually destroying them, and it would be good to keep the amplifier reasonably low noise.

Seems to me (as a circuit designer) that it would be fun to play with turning that amplifier stage into a bootstrapped cascode, which can reduce the input capacitance by a whole lot and also make for very low distortion.

I'm a little puzzled by your question starting, "I wonder why they...". In the circuit "CA" pointed to, the loop is optional. The primary configuration, as I read it, is a very short dipole.

Cheers,
Tom

Exactly right. I saw this little problem as a riddle in a ham magazine about 20 years ago. But the writer didn't give the answer to "where did the missing half of the energy go?" He just speculated that it may have been radiated.

The problem stuck in my head and I finally did the math. It turns out that all you need is plain old circuit theory--no radiation required. The interesting thing is, you can say, "let the resistance be arbitrarily small," and it doesn't matter--half the energy will be dissipated in the resistance.

I don't see why it would not work. Many devices send DC up the coax
with the RF.
Lots of time it is just a mater of adding a RF choke and maybe a
capacitor on each end.

I have just picked up a Cushman CE-50 that seems to have a bit of a problem. I cannot seem to receive a signal thru it even though the squelch seems to work. I also seem to be able to generate a signal OK and the modulation circuits seem fine. I have the manual but it doesn't seem to be very complete with the serviceing information. Can anybody help or point me in the right direction. Thanks Don KB6GQA Please respond via email.

I just found out today that National Semiconductor is obsoleting my favorite op-amp - the LM3900. This was an unusual device, a Norton amplifier, with current-differentiating inputs which made is extremely easy to design complex active filters with. Stock up now, lads, while any inventory remains.

Okay, so what happens if my original capacitor was really two 1/2 farad
capacitors in parallel, and the way I got them charged to 2V was by
connecting them in parallel, and what if I had done that over and over
again...

In fact, there is no oscillation, no significant radiation, and no
significant heating. There is work done, of course, but why let this little
detail interfere with a brand new interpretation of physics?

> step, even though the EM equations are still "linear."

How do you figure? The dielectric "constant" is not a
constant. It's only convenient to use it that way for most
things. It's actually an increasing function of frequency.

> (And in the case of an air/glass interface, WHERE
> exactly is the "step"? Isn't it spread out over
> 1/4 wavelength on either side of the interface?

In classical terms, yes. In light-is-aparticle terms,
the 1/e value at 1/4 wavelength is the same as the fractional
number of photons falling with that distance as determined
by the fractional area under the probability curve.
Pick a description. Dont mix them. For the millionth
time. While one can switch at will in principle, some
things just dont work as intuitively in both descriptions.
When uncertain, use what you know well enough to be correct.

> Think in terms of the evanscent waves in the air
> when light suffers internal reflection within glass.)

And the idea works so well, that quantum mechanics allows
tunneling while no classical wave picture will.
>
> Which one? The lossless coil?
>

How about using the outer capacitor to achieve the conditions
you want and then claiming it may be so far away and "loosely"
coupled as to be unimportant? That's like charging up an
electric car 6 hours every night and claiming the six
hours you arent driving the car cant affect its performaance
because you were sleeping and weren't anywhere near it.

"Extremely difficult to calculate" but interpreted as
what you expect if you could, doesn't mean what you expect
will turn out to match the exact result if you ever manage
to calculate it. Otherwise, solving problems would be easy
since one always expects something.

If you're lost, then I certainly am. I've just rebutted
points you've made in detail. You haven't found anything
to show andy calculation is wrong, or any claims I've
made are wrong. But, feel free to do so in the context
that I made them. Since I can only guess how you plan
to leverage unqualified agreement with the assertions
on your page, I don't intend to have to stop and argue
about any assumptions that I connsider to be implicit.
That's why I provided explicit qualifications. If you
have to get an answer that would be wrong for some contrived
situtation, too bad.

> of thinking that, but if you read my posts, you'll see that
> this is a straw-man argument being used by others to argue

It would be a straw man only if it were obvious why your
description (not an actual antenna) shouldnt violate
conservation of energy. But, you haven't addressed it,
so I expect that's why you get so many questions about
it.

> against the importance of the electrically-small resonant
> antenna concept! It's really silly. To defeat the
> horrible crackpot who insists that this interesting effect
> is part of conventional EM, they attack some totally

OK. Prove your assertion. Calculate how much "suck" your
antenna gets. Then the result can be compared with the
old fashioned antenna. I'll of course have to do the

calculation the old-fashioned way - on my abacus.

> webpage, hang out on PHYS-L the college physics education
> forum, play "science guy" for the MADSCI project, and my
> passion in life is to construct physics explanations which
> can be understood even by grade school teachers. Hence
> all my non-math mental models and visual representations.
> For a REAL challenge in physics, try explaining it to your
> grandmother! There's an Einstein quote about that. For a
> sample of my work, see:

And if you cant answer my questions, which are not
even mathematical, then perhaps your explanations
are wrong. Simplicty is only useful if the simplification
doesnt obviate the resaon for making something simple.

At least you're consistent. Why is there an advantage to
replacing a perfectly inadequate explanation for something
with one that is also inadequate and somethimes unnecesarily
obtuse? In each of the sections below, and others, you've
offered an alternative explanation not one which is more
"correct". That's all well and good up to the point you
start making claims of correctness (Corrollary: if
you don't like nitpicking, don't nitpick unless you
pick all of the nits). Most people will never care not
miss much in life by not understanding physics to a minute
detail and for them, a reasonable physical picture of
what happens, for example during a head on collision,
is fine. In most cases, your explanations are fine. They
aren't necessarily better or worse than the ones you dislike
(some are, some aren't in my opinion), because you only
replace one vague term with a different one. That may
help some people. But, there is not a single explanation
that is fundamental. All of the items are phenomenological
and despite this, you treat them as being fundamental.

Hence the consistenct with this thread. You consider your
antenna "size" to be a fundamental property, but you wont
actually deal with its behaviour except in terms of
phenomonology. "Somehow the nearfield...." just doesnt
cut it. I can obtain any physically realizable result
your setup can produce without appealing to something
I cant explain. It may require thinking about it to
avoid self-delusion, but so far nothing you have attributed
to this antenna falls outside of halliday & resnick physics.

Feel free to not explain why the same results from
doing business as usual is somehow incorrect or please,
nitpick my analysis (uninterpreted - don't dispute
what you think I said). I don't post without caveats
if I think the content is dubious.

You, on the other hand are flat out stating that none
of this can be impedance matching while you've shown
(in the same posts even) that you have a very limited
view of what impedance matching may be. How do you know
it isn't impedance matching if you dont recognize
several commonn examples or if you think filters are
frequency selective for some reason other than
storing energy?

>
> MISCONCEPTIONS SPREAD BY K-6 SCIENCE TEXTS
> http://www.amasci.com/miscon/miscon.html
>

(1) You can add astitine (At) to the missing elements.
It's a halogen.

(2) The action-reaction statements are at best misleading
and more appropriate for a page having to do
with reading old works. You've taken a simple
physics concept and made it obscure with some
notion of what newton intended, not what it
really means. There are always action-reaction
pairs. In your skate board example the force
exerted on the skateboard by the user is the
same as the exerted on the user by the skateboard.
The center of mass never moves. F = 0.

(3) (why do you make something simple convoluted)
Gasses do fill their containers. You just dont
want to consider a denser gas or any other
gas as the equivalent of a container despite
the fact that the same electrical forces prevent
the expanding gas from filling the space occupied
by the container.

(4) Your "cars and planes are not slowed by air
friction" answer is no more correct than the
one you claim is wrong. The correct answer
is that the random thermal motion of the
air produces a net force if you are moving
relative to the center of mass motion of
the air around you. The probability of striking
molecules in the air in the direction of motion
is greater than from behind. Your swirling
and turbulence only removes the problem back
a step since you don't say how that can
have any effect except by the air friction
explanation you claim is wrong.

(5) Electric charges aren't visible unless you know of
some elementry particles that carry charge and
happend to be about 4000 Angstroms in size.

The effects of smaller things like electrons
may be visible under the right conditions,
like when the air subsequently recaptures electrons
that are ionized by collisions from electrons
accelerated in an electric field (you and your doornob
after shuffling across the carpet) Cant see the
charges themselves though.

In any real circuit there is resistance. When one capacitor
exponentially charges up from the other the 'lost' energy is
dissipated in the resistance.

The loss is the same regardless of the resistance value. The higher
resistance values just take longer to do the job.

In the ideal case, of lossless capacitors and zero-resistance wires (but
neither can have zero inductance, of course), there is indeed continuous
oscillation and radiation, but there is no heating, of course, because
there is no resistance. In a real experiment, there may be all three,
but up to two may be of negligible significance.

You can, after all, do the experiment, using, for example, 100 nF
polystyrene capacitors charged to 100 V, and you can verify the result,

even detect the damped oscillation and radiation.

This sort of thing is done all the time. The biggest limitation is the length of the cable and its effect on the quality of the digital signals (keep data speed low). All you need is a "splitter" at each end to keep the RF out of the digital and vice-versa. Simple L-C networks work fine for most HF applications. Generally the RF can be AC-coupled and the low-frequency digital stuff isolated with an RF choke, which will preserve the DC.

Good luck!

Actually this is a DATA radio, sending back physiological measurements.
It already weighs too much at about 8 ounces, so it's going to be in a
waist or fanny pack, whichever causes the least discomfort for the
marathoner. The antenna is likely to be just a quarter-wave piano-wire
spike at the end of the cable (maybe with a "bazooka" matching section
if we can find light enough material).

One of the problems of using a GPS unit on a rocket is that most commercially available GPS units will not function while moving at over a certain speed, nor will they function above a certain altitude (This was an intentional design feature since the government didn't want to allow just anyone to build a missile which used GPS for its guidance system!). I know that some of the balloon launch groups have had GPS failures when their balloon carried GPS receivers reached a certain altitude. Thus, GPS on the rocket may not be the best solution.

I think the technique you proposed will work, although calibrating the receiver clocks will be non-trivial. Plus, if you'll check the specifications on GPS, I think you'll find that the vertical resolution is rather poor in the mode it normally operates in (non-SA?). The horizontal resolution is rather good, but the vertical resolution can drift by up to 1000 feet (if I'm remembering right). You'll have to factor in such differences in the altitude of the receive stations, although you might be able to use a differential GPS approach to minimize the effect.

In any case, the trickiest part will be obtaining the timing signal from the GPS and using that to time the reception of the signal. This will involve some custom hardware (There's no way that you'll be able to get a signal out of a GPS unit and into a computer with anywhere near a 100 nanosecond accuracy.).

One idea I've toyed with in the past would be to mount a repeater on the craft (balloon, rocket, whatever). Then, using an approach like radar, only with an active reflector, you can time the propagation from each of several stations. For example, ground station one transmits a pulse. The repeater on the craft receives it and retransmits it. The ground station receives the signal, and is able to accurately measure the amount of time between its transmission of the signal and the reception of the signal. This lets the ground station determine exactly how far away the craft is. And, note that since the received signal is on a different frequency than the transmitted signal, it is not necessary to switch the transmitter on and off rapidly, nor is it necessary to switch the receiver on and off rapidly. The receiver may be left running while the transmitter is keyed. Additionally, it may be useful to use a modulated signal rather than just watching for the carrier.

By measuring the doppler shift, the gound station can measure exactly how fast the craft is moving away from (or toward) the ground station.

In operation, each ground station would repeat the process (e.g., on the 0, 3, 6, 9, etc. seconds, ground station one performs the measurement, on the 1, 4, 7, 10, etc. seconds, ground station two performs the measurement, on the 2, 5, 8, 11, etc. seconds, ground station three performs the measurement.). Or, if a linear transponder were used on the craft, slightly different frequencies could be used by each ground station, allowing measurements by all the ground stations at the same time.

The simplest measuring device might be a good two channel oscilloscope with a good timebase. One channel would monitor the transmitter output, while the other would monitor the receiver. I'm sure a more elaborate system could be devised if a little custom hardware could be built.

There may be other variations on this approach. One alternative would be to use a passive reflector on the craft and use a pure radar approach, although the power requirements might get to be a bit excessive (although the use of a corner reflector on the craft might help). A similar approach could be done using lidar (laser based radar). One of the advantages to going with a passive reflector, instead of the active repeater, is that since the craft would not be emitting any signals of its own, the identification requirements would not apply to it (e.g., Only the ground stations would have to identify, and it is presumed that there are no weight requirements there.).

If you have an extremely accurate way of measuring the elevation of the signal (and, I mean much more so than what you would have using a simple beam antenna), you might be able to determine the position/altitude using just a single ground station (e.g., You'd know the distance, elevation, and azimuth, and that uniquely identifies the position.). One idea for some thought would be to use a UHF uplink which, when received on the rocket, caused a strobe light to flash. By measuring the propagation delay, you'd know the distance exactly, and you could use optical means to measure the azimuth and elevation (assuming that there was no cloud cover, but most areonautical rules that I'm familar with restrict rocket/balloon launches when there is cloud cover). Or, you could use a radio approach to measure the distance, and use a randomly flashing strobe to optically measure the elevation/azimuth.

Of course, the very first thing you should do is to do some research to see if any other group has already solved this problem. I'm aware that there's an amateur rocket group in Denmark which is fairly active and which has published a bit of literature:

http://inet.uni-c.dk/~dark/

Additionally, there are quite a number of groups launching balloons with radio equipment on board. I don't have a good reference for these, but there are some links from the AmSat page:

http://www.amsat.org/

In any case, it sounds like a fun project. Thanks for the pointer.

Dave

Assuming the transceiver is actually supposed to respond to low input voltages that way, the lowest-tech way around this would be to add a single cell (2V) to the battery supply. Single cell lead-acid batteries may still be available in surplus (if you see some, let me know), or you could use gell-cell batteries such as those made by Gould. I've seen (and owned) 2V gelled electrolyte batteries and they're still listed in the catalogs. New large ones are in the $30 range, I think.

>variable capacitor?

The 100 pf capacitor is the bandset/main tuning. It is used to get you close to the desired frequency.

The 15 pF capacitor is the bandspread tuning. It is used to actually tune signals.

In most designs, the coil and the two capacitors are all in parallel. The stray capacitance in a circuit of this type will be on the order of 10 pF, and the minimum capacitance of the capacitors will total about another 10 pF. So the tuned circuit will have a maximum C of about 125 pF and a minimum C of about 20 pF. That's a 6 to 1 ratio of capacitance, which means about a 2.5:1 tuning range per coil. For example, a typical tuning range might be 2 to 5 MHz.

You can see that the tuning rate of the bandset capacitor will be about six or seven times that of the bandspread capacitor.

> I have a 5 to 1 reduction drive dial, which
>capacitor do I put it on?

The bandspread (15 pF) capacitor. Here's why:

The reason for using two capacitors in parallel in this design is to allow you to cover a wide range of frequencies with relatively few coils, yet also have a reasonably slow rate of tuning. In the above example, the main (bandset) tuning capacitor will have a tuning rate of 6 MHz/turn (because it covers 3 MHz in a half-turn). The bandspread tuning capacitor will have a tuning rate of about 1 MHz per turn.

If you put the reduction drive on the main tuning, you will reduce its tuning rate by a factor of 5 - to 1.2 MHz per turn. That's about the same as the bandspread rate, which defeats the purpose of using two capacitors! And that tuning rate is way too fast for easy tuning.

But if you put the reduction drive on the bandspread tuning, its tuning rate is reduced to 200 khZ/turn, which is not too bad.

The whole point of the design is to reduce the tuning rate. Putting the reduction drive on the bandset cap defeats the purpose of having two capacitors.

Of course, if you can get two reduction drives, put one on each cap.

In all of the two-dial designs I've seen, the best reduction dial is on the bandspread cap. The first regen I ever built had the reduction drive on the bandset capacitor - it got rebuilt after a short time because it was all but useless because of the high tuning rate.

Building regens is easy. Building good regens is not so easy.

What design is this receiver? What tube is used, and where did you get the circuit?

Of course!

I keep saying that there is nothing magic about
this concept. In response, people angrily tell
me that there is nothing magic about this concept!

A really weird controversy.

All I can do is assume that they've come into
the middle of the thread, and didn't notice all the
earlier messages which angrily attack the stuff on
that website, or which angrily state that small
antennas CAN'T interact strongly with longwave
radiation, resonator or no. (It's supposedly a
violation of physical laws because the bandwidth
would be too narrow, or because such antennas must
emit all of their stored energy within a single cycle,
or because antennas REALLY absorb photons, not
waves.)

Sheesh!

Huh? In my previous message I said this:

The total energy in the earth/ionosphere
system is not that huge, its something like
tens of megawatts.

Yet in your message you (again) start talking about
perpetual motion machines. I'm not discussing
"PM." I've never made claims about perpetual motion
machines in ANY of this "energy sucking" business, or
in regards to electrostatic motors powered by tall
vertical antennas, yet you and others keep bringing
up the topic, and so I keep responding with objections.

This stuff about electrostatic motors has little to do
with any previous thread, except that it's again equating
the things I mention with "perpetual motion."

ANYWAY, what I was disputing was this:

bilge wrote:
> you can't extract the energy stored between the
> plates of a capacitor without placing something inside
> that can change the electric field at no energy cost.
> The only way to "tap into it" implies perpetual motion.

This is wrong. It is perfectly possible to "tap into"
the energy stored in the earth's capacitor, so
my reply was to explain why these "sky powered"
electrostatic motors really work. To tap into it
just requires taking advantage of the electrical
resistance of the atmosphere (and throwing away
significant energy in the process.) Such motors are
impractical for most any use. They are laboratory

curiousities only, and science projects for children.
But they have no relation to perpetual motion machines
or "maxwell's demon" phenomenon as you stated:

> The only way to "tap into it" implies perpetual motion.

> I dont believe I've ever encountered someone that deliberately
> misunderstaands at every opportunity just to insure no information
> ever flows in. Is there some advantage to mis-stating what
> someone tells you just so you aren't stuck arguing with yourself?

I responded because of your above statement about PM,
and these statements below :

bilge wrote:
> The most you could do is to try and take
> advantage of the fluctuations about the stored
> energy, not the absolute value of the total. If you
> want a better way to become frustrated, try maxwell's
> demon or szilard engines as an example of just
> how non-obvious the gotchas can be.

bilge wrote:
> But, you forgot that you have to supply the lift to
> place the wire there. This isn't an insignifcant point
> because the same energy that separates the charges
> that give rise to a potential difference, must be
> overcome to keep the wire there.

Why is the lifting of the antenna important? **IF** the
atmosphere was a perfect insulator, your arguement
would be valid, because the motor would only run while
the antenna was being raised or lowered, and the energy
which spins the motor would come entirely from the work
done in moving the antenna. Hence there would be no
tapping of the stored energy in the earth/ionosphere
capacitor, and if I claimed differently, then I would
obviously be a perpetual-motionist crackpot. Looks like
a pretty clear argument to me, and so I responded
by arguing that is real physics, not perpetual motion.

PS, I **AM** a perpetual-motionist crackpot, so if
you want to point this out, it's easy enough to do.
Just take a look at my website.

Either I see holes so obvious that I ignore the arguments,
or your arguments are accompanied by extreme hostility
and not a little sneering, and discussion (for some
mysterious reason) is diverted again and again into
trivia and sudden changes of subject.

I've encountered such behavior before. It indicates a
person whose great fear is to lose an argument to an
"inferior mind" in a public forum, or to have to admit
to the smallest error publicly. These encounters are
very common on newsgroups, and are always a no-win
situation.

If my estimation of your character is way off base, then
show me that I'm wrong: ditch the immature flamer crap.
Demonstrate the extreme self-honesty that's part of
"Scientific Integrity" as Feynman outlines very well
in his CARGO CULT SCIENCE article. Drop all the
defensiveness, be prepared to confront the errors in
your own arguments as well as mine, and to publicly say
the words "I'm wrong" when the situation calls for
it. And I will do the same.

> and so far, no one, yourself
> included, has pointed out an error or inconsistency in what
> I've posted.

True. Whenever you become angry and deliver insults, I
refuse to respond, and you "win" the fight.

If you can participate in a rational discussion without
using ridicule as a debating tactic, or bursting into anger,
then I will address your objections. If not, then emotion
defeats reason, all communication is pointless, and again

you "win" the fight.

Also, your messages lack a .sig or even a name, which is one more reason for me to not take you very seriously. Are you associated with an academic institution? Working in a particular department? Why hide it? You come across as a fairly young physics grad student with plenty of theoretical training but not many years of real-world science yet under your belt. If this is not true, I'd like to know what the true situation might be. I might respond to you very differently if you acted somewhat professionally, rather than remaining concealed behind newsgroup-anonymity.

As for me, I'm a forty year old electrical engineer (see resume on my website) with a passion for explaining science, (especially physics, especially EM) to the public. "The public" means grade-6 level, the same level of understanding at which the New York Times is aimed. That means VISUAL/INTUITIVE explanations wherever possible. That means I must constantly strive to think like a 6th-grader, yet understand the subject above the undergrad level.

This "energy-sucking" subject is of particular interest to me because it contains a visual/intuitive explanation for both AM portable radio antennas and simple crystal radio operation. Are such things disgustingly primitive, and beneath the consideration of "real" physicists? Not if those physicists are educators, and not if they take seriously the Einstein quote "You really don't understand something unless you can explain it to your grandmother." What is "energy sucking" good for? It is something visual that the public can understand, and probably will find intriguing.

A sample of my "science Q&A" at the MAD SCIENCE project: http://www.amasci.com/amateur/answers1.html

Using math to explain physics to the public is like the physicians of past centuries using latin. Obviously it's a total necessity for communication and understanding within the profession, but when communicating with the public, it easily becomes a route to superior posturing and ego-gratification. Feel free to see me as a lowly 6-th grader. However, if this gives you feelings of disgust or haughty superiority, the problem is not with me.

> No one claims a resonant antenna violates any known
> physical law.

Let's see. I recall pointing out that a small resonant
dipole develops a very strong local e-field because
the antenna intercepts incoming EM waves, then it
stores this energy in its LC circuit, and the stored
energy builds up over many cycles, resulting in a
high voltage across the LC circuit and an intense
e-field close to the antenna.

You said no, this is wrong because any energy received
during one half-cycle is entirely radiated away during
the next half-cycle.

I don't know what to make of this. What is your
intention? Look at the implications of your argument.
You are arguing that a small resonant antenna
is a scatterer only and no energy is absorbed (i.e.
it does not act as a radio antenna at all.) If you argue
that small resonant antennas simply don't work, yet others
send me quotes from antenna-design texts describing their
common applications, then I ignore your arguments as
hopelessly flawed and am led to wonder what your
intention was.

You earlier used a similar argument regarding atoms:
that an atom must emit its EM energy within the time of
a single cycle. But look at the implications of your
assertion: the duration of the emitted EM wave would be
so short that its spectral line width would be enormous.
The narrow line widths of atomic emissions lead to the
conclusion that when atoms emit EM waves, the number of
cycles in such a wave is large, not n=1 or n=0.5. How
narrow are spectral line widths in practice? How many
cycles of an EM wave are associated with typical
optical linewidths in, for example, low pressure gas
discharge lamps?

Just look at a mercury vapor arc lamp, with it's very
UN-cooled atoms and their short times between
collisions. Gabor was doing holography using such a
light source, and the temporal coherence is somewhere
around 1mm more or less. Those excited mercury atoms
each emit coherent wavetrains with lengths of at least
a few thousand cycles. Your viewpoint on how atoms emit
photons might be correct, but your descriptions of their
EM waves is significantly different than the stuff
in physics textbooks. Again I must ignore your
arguments, and wonder what the heck is going on in your
head, and what your goal might be in presenting
such arguments.

> I can
> safely say an antenna that works, doesn't violate physical law.
> The same cannot be said for your explanation of how it works.

Then we can agree on SOMETHING.

I've never done this experiment at 100V, but I've done it at 1V and under, and this kind of charge transfer forms the basis of switched capacitor filters. The inductance in this case is negligible compared to the resistance, but that would be true even if the resistance were near zero. The wires are a few microns long, and the inductance is most likely in the pH range. Given that there's some finite resistance, the oscillation due to wire inductance is negligible.

What I was really objecting to was the contention that the energy difference must have been radiated into space or dissipated in resistance. It takes work to increase the voltage on the new capacitor from 0 to 1V, and in an ideal sense, this work is equal to the change in energy of the systm.

Thanks for the additional info, Reg. It is important to be clear about the type of device we're discussing. I hadn't ever bumped into the question before of how accurate the "through-line" type meters are.

You can find specs on things like the Bird 43 meter, but it doesn't attempt to measure forward & reverse simultaneously, nor does it have a scale calibrated for SWR. I've seen people use back-to-back Bird line sections to do the job, and a quick scribble tells me that +/- 10% accuracy may be obtained if the SWR
isn't too high, and if you're near full-scale. If, if, if... so 20% is probably
more typical, and I can see it getting even worse than that.

It's good to note, though, that SWR meters, if they're well built and adjusted, do a
reasonable job of indicating the SWR minimum and whether you're at least in the ballpark of 1:1. The accuracy suffers most at higher SWR.

Because it's the same forces that require you lift the
antenna created the capacitor in the first place
by establishing the hegiht h that the atmosphere
maintains the the charge that produces the potential.
That means the equilibrium position determined by
gravity, temperature, and so on. I maintain that no
scheme is possible that would bleed off enough charge
to change that equilibrium position with out expending
the energy than one gains.

> which spins the motor would come entirely from the work

SH - where you are going wrong (in my opinion) is that you have selected a very simple antenna system which is perfectly calculable with well known formulas that anyone can get out of a textbook. You are then choosing to ignore that and invent a whole edifice of "look at this amazing effect" with a lot of arm-waving and ineffectual arguments. Ineffectual because they fail to quantify what is happening, whereas the old-fashioned explanantion quantifies it perfectly. Small antennas can have large capture areas. They might also have very high Q and small bandwidth. Nothing new here. What's your problem? Is this going to lead us anywhere?
Alan

2662. Grounds

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-30 00:00:00 UTC
From: W2EB <n2tpaNOn2SPAM@juno.com.invalid>
Message-ID: <30264000.de869f54@usw-ex0102-013.remarq.com>
Source record: 61767

I know the three main purposes of grounding: Lightning
protection, safety from "hot chassis", and RF reduction. How do
these grounds interconnect? Do these grounds interconnect?
My shack is a separate building about 100 ft. from the
house fed by 120V three wire (hot, neut, and ground). I have a
ground rod driven at the shack. Do I want to tie that ground to
the house ground that enters my shack? I fear that a lightning
strike at the shack will be more likely to do damage in the house
if I tie them together. Leaving them separate will still leave
the Power supply tied to house ground for safety, and leave the
P.S. minus line (and all equipment chassis other than the P.S.)
tied to shack ground to divert lightning energy. The NEC isn't
clear on this, as it can either treat my shack as just another
room of my house, or a separate building that needs it's own
grounding system.
Otherwise, I assume that lightning and RF grounds are very
similar in construction and must be bonded at the ground rod.
Anyone have any thoughts? Any electricians out there?

73,

Bill
W2EB

Science Hobbyist said some stuff about

> I've encountered such behavior before. It indicates a
> person whose great fear is to lose an argument to an
> "inferior mind" in a public forum, or to have to admit

So far, I haven't been given one to lose. I don't recall
ever making statements that I have any special insight
no one else has, I dont promote any opinions in the
traditional keelynet "einstein was wrong" fashion. In
short, you've had every opportunity to address the
problems with your antenna without any of "The
Great Mistakes of Physics" self-aggrandizement. So far,
all you've done is avoid dealling with the considerable
objections to your model of hpw you think your antenna
works.

> Also, your messages lack a .sig or even a name, which is
> one more reason for me to not take you very seriously.

And it can't be important to anyone without a reason. I don't
really need you to take me seriously. What I post is either
valid or it isn't. I don't limit potential corrections
by comparing sig blocks or checking qualifications.
I also don't feel obligated to just take someone's word
that I've made an error. If you think something is incorrect,
then you should at least be able to say why.

> Are you associated with an academic institution? Working
> in a particular department? Why hide it? You come across

Because it is irrelavent. Usenet it usenet. Who I am
changes nothing about the value of anyting I post.
Loudly proclaiming credentials usually is inversely
proportional to the knowledge of the person that
is proclaiming them. There's nothing more useless than
the post from a person with a sig block full of
credentials , longer than the answer copied from the
pages of a book.

> as a fairly young physics grad student with plenty of
> theoretical training but not many years of real-world

Suit yourself. Theoretical knowledge doesnt evaporate with
age. Only the desire to retain and expand upon it does.

> professionally, rather than remaining concealed behind
> newsgroup-anonymity.

Grandma probably didn't try to turn the explanation
into an APS talk.

> route to superior posturing and ego-gratification.
> Feel free to see me as a lowly 6-th grader. However,

My mistake. If that's what you wish. Ask again about
the antenna around 2006.

> if this gives you feelings of disgust or haughty
> superiority, the problem is not with me.
>
You are the person with the site exclaiming the multitude
of "incorrect" explanations that you have "rectified"
with "better" ones, not I. The fact that you trash perfectly
reasonable and picturesque descriptins of physical
processes as a means of self-promotion speaks to that
issue.
>
> Let's see. I recall pointing out that a small resonant

> energy builds up over many cycles, resulting in a
> high voltage across the LC circuit and an intense
> e-field close to the antenna.

What does "strong" mean? Your definition of intercept is
somewhat "non-traditional", since it involves intercepting
more radiation than there is in the solid angle it's area
subtends. The energy isn't stored over many cycles and
a high voltage does not require that it be nor is a potential
difference stated as a "high voltage" in any way sufficient
to say anything about an electric field. That description
might as well be about a cuisinart. You've resisted all
efforts to pin those things down unless everyone first
agrees that you are correct. Since you cant make such claims
based upon what you have provided, it's incorrect. It

has nothing to do with resonant antennas until
you provide enough detail to turn it into one.

> You said no, this is wrong because any energy received
> during one half-cycle is entirely radiated away during
> the next half-cycle.
>
and...

> is a scatterer only and no energy is absorbed (i.e.
> it does not act as a radio antenna at all.) If you argue

No, I'm not. I'm arguing that if X strikes the antenna and
Y is able to be removed for use, apart from joule heating,
the remainder, X-Y gets reradiated. That's considerably
different than stating you want Y power and resonance will
help your antenna reach out and get more or that any energy
you can possibly store over longer than 1 cycle is of
any value (after a cycle, it's called equilibrium).

> that small resonant antennas simply don't work, yet others

I made no such comment. I said "energy sucking" as a
conceptual basis for one is misguided.

> send me quotes from antenna-design texts describing their
> common applications, then I ignore your arguments as

At this point, I'm beginning to doubt you understand
enough to comment. Or at least comment on something
relevant.

> hopelessly flawed and am led to wonder what your
> intention was.
>
So flawed in fact, you cant point to more than zero
of them. Apparently the cfa is nominally functional,
too. That doesn't make the explanation of how it works
any less wrong.

> cycles in such a wave is large, not n=1 or n=0.5. How
> narrow are spectral line widths in practice? How many
> cycles of an EM wave are associated with typical
> optical linewidths in, for example, low pressure gas
> discharge lamps?
>
Can you say detour? Is this 20 ways to avoid your antenna?
Come back to this when finish the first topic.

> photons might be correct, but your descriptions of their
> EM waves is significantly different than the stuff
> in physics textbooks. Again I must ignore your

Of course it's different. What point is there in simply
repeating the un-illuminating explanation that prompted
the question? Any idiot can tranfer a few lines from
a book. Providing additional information in the context
of the question that is also correct is more effort, less
likely to be found in the particular context in which
the question was posed, but more likely to be useful.
It's pretty useless to learn something without being able
to apply it in any context that it's useful.

> arguments, and wonder what the heck is going on in your
> head, and what your goal might be in presenting
> such arguments.
>
Obviously, not a goal that met with any success.

>
>> I can
>> safely say an antenna that works, doesn't violate physical law.
>> The same cannot be said for your explanation of how it works.
>
> Then we can agree on SOMETHING.
>

Then what's your problem? Everyone else already agrees that
your explanation is wrong. If you agree it's wrong, why
are you arguing that it isn't?

No, it isn't. That's the point. If you assume zero resistance and
inductance, the conservation equations E = CV^2/2 and Q = CV lead to
different answers for the final voltage. That is the apparent paradox
that needs explaining, and the explanation is that, even with
superconducting components and lossless dielectrics there is always
inductance.

Don't sweat the grounds that much. Sink a ground rod and it will do the job for lightning and rf. It's not your responsibility to ground the power line but if that line is connected to the chassis of your transceiver it's okay.

If you have a good ground for rf it will work for lightning too. However, if a storm brews, it's wise to unplug everything, antennas and power cords, until it passes. Ground any unplugged antennas; a strike on your antenna must find a path to ground or it will arc all over the place. You may fry your coax but that's a small price to pay to save other stuff.

2675. WTB: Homebrew cw/am xmitter

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-30 00:00:00 UTC
From: rs2bk@aol.com
Message-ID: <20000330110945.15983.00000032@ng-cj1.aol.com>
Source record: 61780

Looking for a homebrew cw/am xmitter from the 40's,50,s
or 60,s. Mabe with a 6146 in the final, rack mounted?
What ever it may be, I may be interested.

Jim w9ud

2676. Re: No-code techies on 10 meter

Yes, he is wrong. By international treaty all amateur radio operation below 30MHz requires a CW proficiently (after April 15, 5WPM). As more countries military and "Coast Guard" no longer requires CW, this may be eliminated from the treaty, but don't expect any thing for about 5 to 10 years. This seems to be the rough time frame the FCC makes major changes.

Yes, but if you do you will HAVE to use a polarized plug and I would use
a Ground Fault circuit. You could drop the voltage with a divider also
I would put some sort of current limiter, i.e. a light bulb, before
everything but the fuse. This would fall into the same family as the
old AC/DC radios from the early 1960. An example is the Hallicrafters
S-120 and S-200. These did not use polarized plugs, but REALLY needed
one.

> superconducting components and lossless dielectrics there is always
> inductance.

But you're not including the work in your energy conservation equations. You can't change the potential on a charge without doing work on it, and you're changing potential here. Here's the way I see it:

From my physics text:

Energy on a capacitor: C * V^2 / 2

Work to charge a capacitor from 0 to V: Q * V/2, where Q is the total charge transferred, and V is the average voltage. Since Q = CV, the work is C * V^2 / 2 (the same as the energy of a capacitor charged to voltage V). In more general terms, the work required to change the charge on a capacitor from Q1 to Q2 is the integral of (q / C) dq over the range (Q1, Q2), which results in (Q2^2 - Q1^2) / 2C.

Here's our problem:

Initial energy in C1: C1 * V2^2 / 2

Work done to decrease voltage on C1 from V2 to V1: C1 * (V1^2 - V2^2) / 2

Work done to increase voltage on C2 from 0 to V1: C2 * V1^2 / 2

Final energy in C1: C1 * V1^2 / 2

Final energy in C2: C2 * V1^2 / 2

Total initial energy: C1 * V2^2 / 2

Total final energy: (C1 + C2) * V1^2 / 2

[Initial energy] + [Work] = [Final energy]

[C1 * V2^2 / 2] + [C1 * (V1^2 - V2^2) / 2 + C2 * V1^2 / 2] = [(C1 + C2) * V1^2 / 2]

Charge is conserved, and the sum of energy and work is conserved.

I really sympathize with Bill's difficulty in making his point...just look at Mark's objections: in the first case, he calls energy sucking "nonsense"..he
then immediately says that there's nothing unusual about it... and then he comes back and says, "How exactly is it supposed to work?"

I really don't know how Bill is supposed to deal with such scatter-brained attacks.
For the record, Bill's website gives a very good qualitative explanation of a fascinating phenomenon that very few experts in antenna theory are aware of. I myself have actually done the calculations, and the power available to an ideal, lossless, small resonant antenna is something like half the power that the corresponding half-wave dipole can aborb. This applies right down to the atomic level.

>is all I ever envision using a amateur license for.

A technician class licence will allow you to operate model radio control transmitters on 50Mhz and above. Most ham RC activity is on 50Mhz. You still need to observe the "gentlemen's agreement" on which segment of the band to use for RC. Check in your area for any beacons, repeaters or other local use before picking your final frequency.

I've used 50Mhz, 144Mhz, and 220Mhz for RC models, but there is no commercial equipment (to my knowledge) for anything except 50Mhz. If you want to operate on the other bands, you'll have to roll your own.

>right down to the atomic level.
>

The question hasn't ever been "does blah blah.... work?", it's been
"how does blah blah work?" More specifically, it has to do with
the notion that the antenna actually has a greater flux through it
by attaching the resonant circuit (the "energy sucking" as it was
christened. If your calculation addresses that, it isn't apparent
and so far nothing has been suggested that would show any difference
to occur for any reason other than good-old impedance differences.
Depite lots of people, my self included, calling it a misunderstanding
of rather ordinary properties of E&M.

Learn to read, idiot. The term "energy-sucking" is *nonsense* precisely
BECAUSE there is no unusual phenomenon described here.

> and then he
> comes back and says, "How exactly is it supposed to work?"
>
> I really don't know how Bill is supposed to deal with such scatter-brained

What are you talking about? I'm asking how it's *supposed* to work
because he never QUANTITIVELY states how much power he expects to
extract from the thing; I'm only looking for clarification. And again,
if you *read* what I wrote you would see that I have no disagreement
with any calculations he's posted; I'm only trying to understand what
the point of it is. Do you understand why he keeps harping on this
subject? It seems that it's really nothing more than a rather tiresome
troll.

> For the record, Bill's website gives a very good qualitative explanation of

> right down to the atomic level.

Correct, but so what? The phenomenon is very familiar to anyone with
experience in antenna theory; it's widely understood (clearly; anyone
with a rudimentary understanding of the subject, even YOU apparently,
can verify the calculations). Again, there's nothing unusual going on
here.

You really seem like an immature little dweeb, David. Why would a
simple request for *clarification* (ie, a quantitative value for the
received power) be interpreted as an "ATTACK"??

No doubt he finds it as fascinating as I do.
I'm an EE with a physics degree, but never covered antenna theory. Besides,
there's a world of difference between a laser and the fact that the
mechanism was explained some 55 yrs previously by Einstein.

Maybe those people three or four decades back who kept harping on about the
wonders of masers and lasers were just tiresome trolls to the physicists who
had known of the mechanism for years.

2689. Scan rate vs bandwidth and span

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-30 00:00:00 UTC
From: LA8AK@online.no
Message-ID: <38e3e33e.179669592@news.online.no>
Source record: 61794

I need to design a scanalyzer (like SB-620) or panoramic adapter
(German or European word for it) to be used on 9MHz ahead of IF filter

The bandwidth should be at least few hundred kHz wide after the ring
mixer of my FT-902.

it should be a formula for scan speed vs span and IF (and video)
bandwidth, possibly dependent on IF group delay

What is the optimum type of filters to use? The SB-620 wasn't
successful with Drake R-4C, this is likely to be that the VFO
(4.9-5.5) is too close to the IF (5.645), so an SBL-1 was used, and I
tried another IF with 4.43361875MHz color burst xtals

Perhaps it is an optimum sort of detectors, too, it may not be
critical, so even an old CA3089 works satisfactorily for the 40dB
dynamic range which seems more than enought for my purpose of just
seing where the activity is

I need to scan 28.0-28.4MHz to cover actual ssb/cw segment of 2m or
70cm, somewhat less for 1296 and higher bands
Believe AM bandwidth filter works satisfactorily for VHF, but might
not work for HF

on 30m the scan needs only to be 30kHz, but it is only cw signals,
smaller bandwidth can be used

Any suggestions?

73 es bcnu
jan-martin

The RG174 cable I have seen is very flexible and has a stranded center conductor. However this stuff has a loss of 31 dB/100' at 1 GHz. You will lose about 1 dB in a three ft length and because of ground plane inefficiency, and shadowing from the head your shoulder antenna will probably be less than unity gain, so count on the configuration being not better than about -7 dBd. Also be aware that you will need to fasten something to keep the dipole vertical at all times. Watch out for piano wire near the eyes.

Are you sure that your system can't work with an integral mounted antenna at hip level? For planning purposes, count on about -10 dBd for this configuration. May be much worse for close in crowding from other runners.

OMs,

Since I do not have SM series mic from Icom, it seems to be a little hard to find right desk mic for my Icom IC-738 Rig.

I tested various dynamic Mics from RadioShack and EV-621L, all produce very low sound quality (very low in tone and mic input).

Any good ideas without buying SM-8 for $ 190.00 ?

Please share your brilliant ideas.

John,

You're right, of course. I realized what you were saying about an hour after I fired off my last post, and although my analysis (in my other post) is correct in terms of energy and work, the thing missing is exactly what work is going on when you tie the two capacitors together. In the end, the work can be dissipated, radiated, or stored, but it has to show up as one of those three in any real circuit.

Damn good thing I didn't become a physicist.

Tom: This is "Ed". I changed my sign from K3FDY. In regard to the comment you query, I was referring to the 1 mtr. diameter Wellbrook loop. If short, dipole-probes null as effectively as a loop, and the sensitivity is equal, it seems to me that the dipole configuration would comprise a less obtrusive package and profile?

Additionally, where do I now find a ckt. for a "cascode" diff. amp.? And I thought life was going to be simple?

Thanks, Ed W.

> > high voltage across the LC circuit and an intense
> > e-field close to the antenna.

> What does "strong" mean?

I mean that the e-field near one antenna is "strong"
relative to the e-field nearby a similar short dipole
antenna which lacks a resonator. Or a "strong" e-field
relative to the e-field near a similar antenna which
does have a resonator, but where that resonator is tuned
far off from the frequency of incoming waves.

> Your definition of intercept is somewhat "non-
> traditional", since it involves intercepting
> more radiation than there is in the solid angle it's area
> subtends.

By "solid angle," I assume you mean that the vertex of
this conical region is to be placed upon the distant
transmitter? By "its area", do you mean the area of
a disk whose diameter is approximately the same as the
length of the small dipole? Or instead to you mean
the area of a disk of 1/4-wave radius? I don't have a
clear image of what you're describing, so I need a bit
more detail.

> The energy isn't stored over many cycles

We disagree on this, but let's save this part of the
discussion for later messages, if any.

> and
> a high voltage does not require that it be nor is a potential
> difference stated as a "high voltage" in any way sufficient
> to say anything about an electric field.

I speak of "high voltage" and "strong local e-field" in
the same breath because I'm comparing TWO antennas, as I

did on that webpage. Regarding those small capacitor plates
on http://www.amasci.com/tesla/nearfld1.html, if there
is 100V potential across those small plates on the right,
then the e-field at a particular spot near the plates
is approximately 100x higher than if the same plates
had only 1v across them. I describe a small resonant
dipole the same way: at resonance, the antenna must have
a "high" voltage, and a "strong" e-field, and off-resonance
it does not. You obviously don't agree. But at least is
my description clearer now?

> That description might as well be about a cuisinart.

Again with the insults. What's the problem? Do you act
so uncivil in real life as well, or is it only when
you are acting anonymously on newsgroups? If you can
take insults as well as dish them out, without flying
into blind rage, then that's different. But if you hate
it when others insult you, then I suggest you cut out
this immature "flamewar" crap. It's very unprofessional.

If you imagine that I'm INTENTIONALLY trying to
explain things in a mixed up way, and therefore it
makes you angry, then I don't know how to solve this
problem, because I'm simply talking, and I'm not
INTENTIONALLY trying to obscure anything.

I think one problem here is a language difficulty: I'm
speaking "electrical engineer", and another engineer
might understand it instantly, while to a physicist it
might sound like intentional gibberish or something.
But explosions of rage are not the solution.

> You've resisted all efforts to pin those things down
> unless everyone first agrees that you are correct.

What? This is silly. What I've RESISTED is responding
to **YOU**, since you keep bursting out in rage, and
angrilly telling me what my own thinking "really" must be,
or what my intentions must "really" be. And these things
are always something foul. (Are you familiar with the
term "projection" in psychology?)

Yet in reality, you have little knowledge of me, and
your negative fanticizing has little to do with me.
However, it certainly does give me an EXTREMELY low
opinion of your character, and it convinces me to avoid
talking to you. If this means that you've "won" this
"fight", then so be it. May you "win" many more such
"fights" in the same reprehensible way.

Others here have made good points, and I've responded to
them (for example, about reciprocity, and about the

reflectivity of "space cloth," and the need for small
antennas to be scatterers as well.)

> Since you cant make such claims
> based upon what you have provided, it's incorrect. It
> has nothing to do with resonant antennas until
> you provide enough detail to turn it into one.

Yet what I'm describing matches some of the information
provided by others, the stuff that came from the antenna
textbooks. We're not arguing about the particular wording
of explanations here. We're arguing about objective reality:
when a small resonant antenna is tuned correctly, is the
"effective area" far larger than the physical area of the
antenna? If you say no, then I must assume that you didn't
read those posts from the textbooks.

> > send me quotes from antenna-design texts describing their
> > common applications, then I ignore your arguments as
>
> At this point, I'm beginning to doubt you understand
> enough to comment. Or at least comment on something
> relevant.

And I think the same of you. One of the quoted textbooks
mentioned that the "effective area" of a lossless small
resonant antenna is L^2/(4pi) where "L" is one
wavelength. Yet that lossless antenna could be physically
100x smaller than a wavelength without changing the size
of the calculated effective area. Do you disagree with
this? If not, then look at the implications: the flow
of EM energy in that relatively large-diameter region
around the tiny antenna must somehow end up inside the
load resistor attached to the tiny antenna. Does the EM
energy magically vanish from space, only to appear in
that resistor? No, it must FLOW INWARDS: if we draw
progressively smaller spheres around that antenna, the
net-inwards flow of energy through the surface of each
sphere must be the same for each sphere. Agreed?
Therefore the watts/cm^2 very close to the tiny antenna
is far higher than the watts/cm^2 a couple of wavelenghts
away. Strength of e and b fields in EM waves is
directly proportional to the power density of the
waves, therefore the e and b fields very close to the
tiny antenna are far stronger than those in the undisturbed
EM waves several wavelengths away. And if the antenna
is 1000x smaller than a wavelength, the fields near
the antenna are that much stronger.

This stuff is TRIVIAL. If you have a physics degree, I
shouldn't even have to explain it, it should be instantly
obvious.

John, ICOM builds a preamp into the mike, so most other mikes will give low output. If you can build or buy a preamp you can use them just fine. Heil makes a small amp for their mikes that would probably work with others, and there are various mike preamp circuits in the handbooks. +8V power is available at the mike connector for this purpose.

Christer, thanks agn:
I didn't know there was so much out there on the subject?
Even though some of the circuits may be a bit involved, they introduce aspects for consideration, like the center-tapped loop? Such as, if a center-tapped loop was used, why couldn't then maybe a simpler, "push-pull" amp. be used with a common source or emitter output?
Apparently if an IC, op. amp. is used as a diff. amp., there still needs to be a positive and a negative power source, whereas, with the two, balanced or diff. amp. circuits Christer presented, there is but a single polarity pwr. source?

Tom Bruhns: I forgot to acknowledge you comment on static maybe degrading FETs while not destroying them. I didn't consider that possibility? Some MOSFETs have built in diode protection apparently. A few picofarads of shunt capacitance can sure shoot-down the high-end freq. tuning range of a high Q resonant ckt., I have discovered. Is there any advantage of a "PIN" diode in terms of shunt capacity?

The two explanations ('energy-sucking' and 'impedance matching') are
really equivalent. You may *prefer* one or the other, but that **does
not** make one of them wrong.

It seems easier to *explain* in words how a ferrite rod antenna or the
'passive amplifier' work by considering 'field concentration' (the
result of the interaction of the transmitted field and that generated
locally by the device) rather than impedance-matching. You can draw
diagrams of 'lines of force' of the magnetic components of the fields.
Primitive but effective. But it is, I suspect, far more difficult to
calculate what happens using field concentration than it is using
impedance matching.

I am surprised not to get any reaction to the 'passive amplifier'. Maybe
everyone who doesn't believe it is going to build one first before
rushing to post? Unlikely, but....

It is often reported the SWR cannot be brought down to better than say 1.1 to 1 even when using an ATU.

If it is possible to obtain an SWR as low as that, then, by a very small readjustment of the ATU, 1 to 1 should be possible. So what's wrong ?

This is not necessarily due to a defect in the meter (the mechanical zero could be offset), or to a limited range of the ATU. It is highly unlikely 1:1 to 1 will occur at the exteme settings of L and C.

The problem is most likely due to the harmonic output content of the transmitter. It is impossible for an SWR bridge in an antenna system to be simultaneously at balance at the fundamental and all the harmonics.

A weakness of SWR bridges is, in effect, their very broad operating bandwidth. But when a noise bridge is used the radio receiver is not just the bridge balance detector, it is also the bandpass filter.

So the annoyance of the impossibility of obtaining a reading of 1 to 1 can be investigated by switching off the transmitter and using a noise bridge + receiver. And Bingo ! You might have had it all the time.

I'm stunned. That makes about THREE people in all of these forums who actually grasp this simple idea. Are experts in antenna theory really so ignorant of this concept? I thought that I'd missed the idea in engineering school simply because I specialized in digital electronics rather than analog. But then I've never seen the antennas in portable AM radios explained in any magazines either, at least not in terms of anything except magnetic pickup coils.

A couple of people here have dismissed my messages as being obvious "self-promotion". Ah, I think they are confused.

How do I benefit by becoming the target of hundreds of newsgroup flamers? I certainly find this sort of controversy of value, but only for the very few people who refuse to descend to using ridicule, who are smart enough to see implications as well as concepts, and who can find the REAL flaws in my assertions.

Here is "self promotion":

BUY NOW! AMAZING ENERGY SUCKING ANTENNAS, ONLY $19.95!!!

Sorry, I'm not selling any. If people really want, they can visit SCIENCE HOBBYIST and shop for books in the bookstore. All profits go to support a local Seattle nonprofit science outreach company which gives science presentations in grade schools. There, now you can accuse me of "self promotion". If this draws attention to the bookstore and makes a few bucks for scienceclub.org, then it's worth the continuing derision.

If by "self promotion" they mean that I'm a blow-hard, then I gladly accept that lable. I started life as a total "brain" or "geek" or "reject." For this reason, my finally rising to the status of "newsgroup blowhard" is a fair achivement for me. If others here are in a similar situation, I suggest that they follow my lead and loudly flaunt their geek-hood. Recall the title of the second

Feynman anthology: WHAT DO *YOU* CARE WHAT OTHER PEOPLE
THINK?" See:

OK, how about something a little more basic; how do you use the
'standard' single meter SWR meter? I assume (always dangerous) that
you peak the forward reading , then switch to 'REV" and read the SWR
directly? Having never had anyone actually show me, I'm not sure.

>not** make one of them wrong.
>
No. Simply because you can picture something in a certain
way and come up with a model doesnt make it correct. This
has nothing to do with an engineering model that reduces
an impractical fundamental description to a model from which
something may be constructed. They aren't equivalent and what
I "*prefer*" is thecorrect fundamental description. Being
right isn't a democratic process decided by voting. Preference
has nothing to do with it.

>It seems easier to *explain* in words how a ferrite rod antenna or the

Easier doesn't make it a correct representation of the underlying
process - only a limiting case of it, recast to facilitate calculation.

>
>I am surprised not to get any reaction to the 'passive amplifier'. Maybe
>everyone who doesn't believe it is going to build one first before
>rushing to post? Unlikely, but....

Or maybe, from the "energy sucking" thread, trying to separate the
question of whether the device works from whether the explanation
is correct or what the limitations of the explanation might be
was deemed futile and therefore pointless.

I want to fill holes in stripped plastic screw posts, then redrill them so that I can re-use the self tapping screws to hold circuit boards in. Can anyone recommend a good substance that might work? I thought about "plastic wood" or some kind of epoxy, but didn't want something too hard or too soft. Thanks.

Normally.

>3) Where is a good place to buy scope probes? The vendor at the
>hamfest recommended probemaster but they don't list the HP-1222A.

The 1222A only has 15MHz bandwidth, so the probes are not very
critical. No point in paying ProbeMaster's prices (you would be
better off putting the money toward a better scope).

I have a list of low cost probe vendors:

http://www.spies.com/~dd/probes.html

>4) Should there be more than one probe available that works with this model,
>what should I pay attention to?

Just buy the cheapest.

OK. So what? For two arbitrary dipoles, the fields will
have some relationship. Attaching components to them
changes the fields they produce. Construct them to have
any relationship you want. It doesnt change the incident
radiation.

> By "solid angle," I assume you mean that the vertex of
> this conical region is to be placed upon the distant
> transmitter? By "its area", do you mean the area of
> a disk whose diameter is approximately the same as the

By solid angle I mean exactly the definition of solid
angle. You can either orient the antenna to make that
simple or difficult, but I'll be satisfied with just
the physical area/4*pi*r^2, with the areal vector along
r.

> clear image of what you're describing, so I need a bit
> more detail.
>
Solid angle is described in countless math and physics
texts and is not an interpretable term.
>
> We disagree on this, but let's save this part of the

V
------- ---------

```
======= <-- 100v ========= <--- 1V
------- ---------
0

V V
========= ===========
\ \
> 100 V 1 V
/ /
========= ===========
0 0
```

The field in both cases between the inner plates is smaller. In all of these, what is the field between the outer and inner plates? I've already mentioned this a zillion times. Fix the plate distance and use THAT capacitance to calculate what real field you get using real time relationships for the charges that appear. You cant pick and choose values and then gloss over. The argument is too sloppy to make difinitive statements about. You haven't yet shown the "small" plates are "small". In fact, "small" depends upon what you take the capacitance to be (and the fact that you have the area drawn differently for the outer and inner plates, means either "small" DOES NOT mean I can ignore fringing fields, or else you can fix it by drawing the plates the same size and stating that or you can fix that by considering ONLY the piece of the capacitor of the same area directly above and below as being in series. The balance of the area of the outer plates is in parallel and "small relative to the big plates" depends upon the initial decision for small which must be consistent with the ratio you choose. I've already said all of this. You cant pick and choose the independent paramaters at will and state the situations that produce them are equivalent and physically realizable. Before you try and call these equivalent, make them PHYSICALLY equivalent to the same antenna. Then, it won't be neccesary to go back to square 1 everytime you assume something. If you cant produce a realistic configuration that pins down EVERYTHING now, then you certainly wont be able to do it further on. Calculate the capacitances by plate area and separation distance. Provide capacitances and fields in terms of sizes so that you don't make assumptions that are based upon physically unrealizable geometries or electrical characteristics that require them.

> dipole the same way: at resonance, the antenna must have
> a "high" voltage, and a "strong" e-field, and off-resonance
> it does not. You obviously don't agree. But at least is
> my description clearer now?

No. Redraw the entire thing with plate sizes. Since the capacitance depends upon that, so do the ratios and so do the fields. I don't know how many times I have to say that the outer plates don't matter for any real result. You can make them matter, but not if you want

to arbitrarily choose ratios of your capacitances and voltages and
have them represent the same antenna as you've implicitly assumed.

> Again with the insults. What's the problem? Do you act
> so uncivil in real life as well, or is it only when

Hard to say. I've never had anyone refuse to describe something
they were trying to describe. Everyone that has ever asked me
about something without knowing enough details to provide the
answer they've wanted has responded to being told what was missing
either by filling in the necessary information or realizing that
once they knew the information wasn't complete, answered their
own question. Just guessing, I'd probably be at least as uncivil
after repeatedly telling them why they don't have a complete
description and having them repeatedly restate the same incomplete
question.

> this immature "flamewar" crap. It's very unprofessional.
>
I'm not a professional. I do it for free.

> might sound like intentional gibberish or something.
> But explosions of rage are not the solution.
>
See it however you wish. I don't see being blunt as flying
into a rage. I see it as an appropriate way to respond to
stubborness for the sole reason of being stubborn. You've
had explanations in practically every terminology imaginable.
I personally addressed the topic in exactly the terms you
provided, but when it becomes inappropriate to use voltages
because charges are what matters for what you've provided,
that's the breaks. As the poster that correctly resolved
the so-called capacitor paradox (without invoking unstated
features), the energy may be given by either q^2/2C or
by CV^2/2, but the right answer depends upon recognizing
whether you know q or V.

> to **YOU**, since you keep bursting out in rage, and
> angrilly telling me what my own thinking "really" must be,
> or what my intentions must "really" be. And these things

You think there's a book deal in it or something?
Get over it.

> are always something foul. (Are you familiar with the
> term "projection" in psychology?)
>
If I'm interested in knowing, I'll check a psychology
newsgroup. This is a physics newsgroup. Provide physics
as asked raather than opportunities to go off on
tangents.

> opinion of your character, and it convinces me to avoid

I don't care what you think about my character. I only
care if you provide a correct description of a problem
so that it lends itself to a correct and unambiguous
result.

> Others here have made good points, and I've responded to
> them (for example, about reciprocity, and about the
> reflectivity of "space cloth," and the need for small
> antennas to be scatterers as well.)
>
No, you haven't responded to anything that didn't allow
you to introduce additional ambiguity.

> of explanations here. We're arguing about objective reality:
> when a small resonant antenna is tuned correctly, is the
> "effective area" far larger than the physical area of the

Not so long as you wont place the proper constraints on
your description you aren't.

> antenna? If you say no, then I must assume that you didn't
> read those posts from the textbooks.

I can quote anything and remove the context to support anything
at all.
>
> And I think the same of you. One of the quoted textbooks

Fine. Take a vote and see whether the consensus thinks so.
Sure, it doen't prove anything, but I'd venture to say
it's more objective than your opinion.

> This stuff is TRIVIAL. If you have a physics degree, I
> shouldn't even have to explain it, it should be instantly
> obvious.

What's obvious is that leaving enough degres of freedom with
different ones being implicit at fifferent times let's you
claim anything down the road. Remove anything implicit.
There's no garauntee "small" means anything without some
constraint on it.

2718. Re: How does an SWR-Meter work?

Newsgroup: rec.radio.amateur.homebrew

From: Ralph Mowery <rmowery@dialpoint.net>
Message-ID: <38E54D64.521AE76C@dialpoint.net>
Source record: 61873

This sort of thing should be on the test..

There are 2 ways that I do it. If I can change the output power of the rig I set the swr pot to the most sensitive position. Then set the transmitter to the lowest power, transmitt a carrier and bring the power up tuil the meter is at full scale, then switch to the reverse position. If I can not vary the output in a smooth way, I put the transmitter on the lowest power I can and then use the pot on the swr meter to get the meter to full scale, then switch to reverse to read the swr. The transmitter can be set to full power, but that creats more 'trash" on the band.

Sometimes the swr will appear to change if low power vers high power is used. There are basically 2 reasons for this. One is the transmitter is generating power (harmonics) at other than the carrier frequency and the antenna is not matched for the harmonic. The other reason is the diodes that is used in the swr bridge are not linear for various power levels.

> OK, how about something a little more basic; how do you use the

As you have no doubt noticed, most of your responders do not believe this idea is safe. If you package the circuitry in a nonconductive (sturdy plastic) box with NO METALLIC PROTRUSIONS, it can be just as hazardous as a table lamp. Does that frighten anybody? You can use a half-wave rectifier consisting of a 400 (minimum) PIV diode and a filter capacitor. Sizing the capacitance on the skimpy side so that the relay coil's current prevents the DC from rising to the peak AC voltage will eliminate the need for a dropping resistor. The required capacitance will depend on the load current, so I cannot tell you how many microfarads you need. You need just enough to allow relay pull-in without buzzing or chattering. The dc voltage will rise to about 150V when you switch off the coil, but will drop like a rock when loaded. This is as simple and crude as it gets, but a 10 - 50 ohm resistor in series with the fuse you should include ahead of the diode would be a good idea. It would limit inrush current. Using a suitably chosen bleeder resistor would improve the lousy regulation, but will dissipate some heat. If you are careful in your implementation, you can build something safe with out a transformer. Good luck.

Source record: 61876

Curtis, A higher power transistor will NOT dissipate any less power
than the 2N3053 for the same level of output power! The physical and
electronic laws are no different in that respect for higher power
devices. Apart from the "bigger silicon", the higher power transistor
would be in a package that can transfer more heat to a suitable external
heat sink --which you would need to supply. It runs only slightly
cooler because of its larger mass, but you must still provide a suitable
thermal path to carry the heat away. What you need to do is provide a
more effective means of removing the heat from your transistor. I am
not familiar with the 2N3053, but being QRP, I would guess it might be
in a small metal case. I believe it needs a heat-sink, but you cannot
afford to greatly increase its capacitance to ground. A good approach
might be a small clip-on sink with a small fan blowing on it. It does
seem a bit wierd to need a fan in a QRP rig though! Hope this helps.
73, Allan.

2722. Re: SWR Goes Funny

Sounds like a problem with the SWR indicator. Perhaps it's getting warm and losing isolation. Open the unit and see what's going on there.

I have three SWR indicators in line at all times and they don't quite agree. The one that is the poorest is in the MFJ 986 tuner. It utilizes a cross needle meter that is poorly calibrated. Further, the rf sampling toroid has poor insulation and gives erratic readings some of the time.

Try another SWR indicator and make a comparison. I don't imagine anything in the antenna system itself is changing.

73, Bob K6DDX

The general recommendation for munging return addresses is to munge the domain name rather than the user name (after making sure the munged domain name isn't actually valid). The reason is to prevent the spam from reaching your domain and requiring the domain to process and reject it.

Of course, when you munge the user name instead of the domain name, you're not causing the domain any greater a burden than those of us who don't munge at all.

I recall a circuit in a major electronics magazine a few years ago that employed an atmospheric pressure sensor and a microprocessor to log the readings into RAM. After the flight, you simply download the flight profile into your PC and convert the pressure readings to altitude. The processor kept time stamps, too, of course. How accurate is barometric altitude determination? Seems like it would be as good as any of the other methods mentioned, and would cover a much greater max height. Just guessing, there, however.

if anyone's interested in the article, email me and I'll dig up the original citation.

What is the expression for the potential energy required
to assemble charges? Yes, it requires doing work to move
them. The reference point is typically infinity. The person
you are responding to has the correct answer.

>Well for the *practical* case, you don't need any complex math. There
>MUST be some resistance, and the missing joule goes to heat it up. For

Nonsense. In that case, even more would be lost. What is:

\integral F\cdot dl = q \integral E\cdot dl

If you move a charge, with no resistance, no dielectric,
no "practical" contrivances, what is the work done, in
taking charge q sitting a distance d from charge Q along
a simple straight line from point d to point d+x?

>energy *may* be radiated away from the oscillating circuit, so that

>inductance from any circuit, however small.

Which doesn't have anything to do with this problem. If
q^2/2C and CV^2/2 don't give the same results, then there
is a physical reason. In this case, charge didn't disappear
but work was done. Which is likely to be the proper form
here?

Who says this is a paradox?!!! And I am tired of hearing about that same old hackneyed junk explanation of interconnecting wires having non-zero resistance. Don't you suspect anything at all when you lose exactly 0.5000000.... of your initial energy? Bit of a coincidence don't you think?-even odder when it results from an fairly indefinite specification of the existence of something. This is a hypothetical set-up and it should be explained by pure analysis. Does the operational calculus help us with this? Well, I should say no if you're constrained to working with garden hoses and golf balls! Is western civilization the only one relying upon promulgating a deceitful fiction for education?- the end justifies the means?

That's an excellent analogy. Two coffee cans with a pipe connecting
them at the bottom and a valve in the middle of the pipe. One can has two
pounds of water in it and the other one is empty. Open the valve and soon each
can has one gallon of water in it. The quantity of water is conserved just like
the quantity of charge in the caps.

Now consider what amount of work you could get out of the can with two
pounds in it, if you let the water out from the bottom to drive a water wheel,
as compared to the amount of work you could get out of both cans when they each
have one pound.

Since the pressure at the bottom of the can with two pounds in it is
higher than the pressure would be if it had only one pound, you get a lot more
work from the one pound of water that comes out first than from the one pound
that comes out last.

The amount of energy stored in the two pound can is greater than the
amount of energy stored in two, one pound cans. Where did the extra energy go?
The amount of water didn't change.

Hmm - is this something like, for the circuit to be critically
damped, the resistance has to dissipate the other Joule? Or
if it's the theoretical superconducting circuit with perfect
dielectrics, it's radiated as EM energy?

That does kind of make sense.

Thanks!
Rich

Yeah, that darn 2nd-order term screws everything up! All the electrons
are still there, and Q=CE still holds, (where Q == charge, C ==
capacitance,
and E == voltage), but the energy is different because somehow 1 Joule
of
work got done, is that it?

I accidentally started a flame war once, which some of you might
remember,
about using a 115V bulb on a 230V line by just half-wave rectifying it.
Got egg on my face when I did it on a spreadsheet and found out that
the power would be 1.4 times the power of running the 115V bulb on 115V.

Maybe I should stick with digital electronics and programming. :-)

Cheers!
Rich

I am NOT a licensed electrician, but I've worked for supply houses and

electrical equipment manufactures for about a dozen years. These are
my OPINIONS only, and do not represent the opinions of who I work for.

OK, now that the weasel words are out of the way, the way *I*
interpret the NEC is that if you shack is a seperate building, it
needs to have a 'service disconect' (breaker or fused switch that is
UL listed as service equipment) and a seperate ground. Further
the ground and the Neutral must be bonded (tied together). The ground
from the house should not even go to the shack.

In pratice, a small outbuilding is often feed from the house, and is
NOT viewed as a sepereate service by the local inspectors. In that
case, I would use the shack ground rod as a RF ground, and NOT tie
it to the house service. This is really up to your local inspectors
judgement.

Clear as mud, right?

Ok, I know that this is a homebrew group, but most here seem pretty constructive and I need some Elmering. I'll give some details and then pose a question. Thanks in advance.

Drake TR-7, less than 1 year out of rehab at Drake.
MFJ-941E Versa-tuner II with SWR meter.
10-15-40m dipole in attic.
CW on 21.140 mHz at ~10 watts output.

The question: After ragchewing at 5-8 WPM on CW for an hour, the SWR as measured by the tuner showe a huge rise, up to around 3:1. The other station noticed no change in strength or character of the signal. Could it be a fault in the meter, or what? Oh, yeah, the tuner doesn't require too much in the way of capacity or inductance to tune the antenna. The MFJ-207 SWR "detector" was used to set the tuner and shows less than 1.2:1. Anybody got any ideas?

Russ Nixon

Hey, kids, I used to think I knew something about electronics,
but this thread is confusing the hell out of me. Wouldn't a
1F cap at 2v have 2 coulombs of charge, and a 1F cap at 0v
have 0 coulombs of charge, and when you connect them together,
doesn't one coulomb go into the other cap, such that they're
both at 1v now? (of course, this is in a perfect lossless
circuit.) I'm thinking of two coffee cans with spigots and
a hose; doesn't it work that way?

Apparently I haven't got enough complex math or calculus
to understand what's *actually* going on.

Thanks!
Rich

Bob,

I tend to disbelieve the SWR meter too, I'm just interested in
what is going on here. Do you thing that 10 watts would give it all
that much heat? Next week I'll try it at 20 or 25 watts and watch to
see when it occurs.

Thanks and 73

You have used Q = CV (conservation of charge Q) to get your result. Now look instead at E = CV^2/2 (conservation of energy E). The 1 F cap at 2 V has 2 joules of energy. When we finish up, IF we do, with two 1 F caps charged to 1 V, the total energy is only 2 x 1/2 = 1 J (joule).

Where did the missing 1 J go? That's the paradox.
>
>Apparently I haven't got enough complex math or calculus
>to understand what's *actually* going on.

Well for the *practical* case, you don't need any complex math. There MUST be some resistance, and the missing joule goes to heat it up. For the *ideal* case of superconducting wires and lossless capacitor dielectrics, the energy oscillates continuously between the capacitors and the stray inductance of the circuit, and to prove that you do really need to understand differential equations. The voltages across the capacitors DON'T end up at 1 V each, they change continuously, and the Q = CV equation isn't applicable in that simple form. In addition, some energy *may* be radiated away from the oscillating circuit, so that eventually the oscillation dies out and the capacitor voltages then do become equal - at zero!

While we do know that resistance of wires can be eliminated by using superconductors, we do not know that lossless dielectrics (e.g. a 'perfect vacuum') can exist and we do not know how to eliminate all inductance from any circuit, however small.

Whether critically damped or not, the resistance eventually dissipates
it.
> Or
>if it's the theoretical superconducting circuit with perfect
>dielectrics, it's radiated as EM energy?

Well, I don't think it's inevitable, but it may be. In any case, the
long-term solution involves the continual exchange of the initial energy
between the capacitance and inductance, and there is no way in which
energy can be lost, other than radiation. So there is no paradox.

If you connect any finite value of resistance between the capacitors, the "lost" energy is easily accounted for as being dissipated by the resistor. If you put the impossible value of zero ohms between the capacitors, an equally impossible infinite current flows. So you're left with the conclusion that the time integral of the product of the zero resistance and the square of the infinite current equal the lost energy. In circuit analysis, these infinite currents are called "impulses", and academicians love to play with them. As a working engineer, I've never found much of a use for them.

Ironically, the first time I ran across this problem was on my PE exam.

Ken,

Now the tough part. What constitutes a separate building,
and what constitutes a "small outbuilding"? I read the NEC.
Clear as mud describes it very well.
I was considering this a "small outbuilding" based on a
couple of things:

a. It's fed with 120V, not 220/240.

b. It isn't separately metered.

c. It's fed from a fuse in my house fusebox. NOT from the main
entering the house.

Right? Wrong?

Russ: I had similar problem with my HB QRP transmitter. SWR looked
good at the start, but when things got warmed up the SWR would
suddenly jump much higher.

In my case the problem turned out to be an intermittently bad final
amplifier transistor. As the thing heated up a bit, it started to
generate VHF parasitics. My antenna had a low SWR at 20 meters, but
not at VHF, so when the VHF energy got into the system, the SWR went
high.

There is an easy way to check for this: Run the rig into a resistive
dummy load and watch the SWR. Becasue the load is now resistive, the
VHF parasitics will have no effect on SWR (the load is the same at all
frequencies). Maybe run the rig until the problem starts, then switch
to the dummy load and check SWR.

Good luck. 73 Bill N2CQR

Every real electical circuit possesses capacitance, inductance,
conductor resistance and radiation resistance.

If one capacitor is discharged into another then the end result is
perfectly predictable according to universal laws which have been
known precisely for more than 120 years. Faraday, Kelvin, Maxwell and
Heaviside. All English except for Kelvin who was a Scot.

Well, you asked: "Would anyone suggest multiple 2N3053's or another device capable of handling the power without producing so much heat?"

This means that you want a device with higher efficiency (more power transferred to the antenna and less heat) but this is difficult to achieve because you are maintaining the operation class that defines the efficiency (then more output power leads to more heat).
The transistor that can withstand higher power is just a bigger one. It is a real luck to get such a transistor with similar parameters (if you use the same external components it may work but likely with smaller performance than the maximum). The heat generated will be the same but that big transistor can work with higher temperatures.
So, I'd suggest you to maintain the same transistor and improve its cooling system, that is, increase the heatsink to eliminate the heat on the transistor itself, resulting in lower temperature.
About the final amplifier you have to see whether it is not being overexcited. In this case, it is probable that you cannot take much more power from it. But if it is only a matter of overheat too, use the same cooling improvement.

I had a similar problem here. Normally interferences of this frequencies
are produced by the horizontal deflection of the monitor (or TV sets).
Firstly, vary the monitor brightness to see whether the birds intensity
varies. If positive, it means that the interference is generated by the
accelerated electron beam (within the tube) because accelerated charges
produce electromagnetic radiation and the beam is accelerated from right
to left and vice-versa during the horizontal sweep. If generated by the
horizontal circuits, the birdies are not brightness dependent.
The solution for my case, that lowered the birdies to very low levels,
was to open the monitor, glue tin paper to the monitor case inner wall,
BUT RESTORING THE OPENINGS ON IT (for heat dissipation) and grounding
the metal paper shield (as the shield must be grounded, the use of
aluminum paper is not recommended).

You could always try checking the result without even using
a circuit:

Allow the first capacitor to drop to 0 volts by taking one
plate to infinity. (This is how it's defined in the first
place). What's the change in energy? Now, bring half the
charge back until you have the original capacitance. Since q=CV,
and C is the same, the voltage is 1 V. What was the change in
energy? Bring the other half of the charge in on the plate to
form the other capacitor so that the voltage is also 1 Volt
(miraculously, this occurs when both capacitances are the same).
What's the change in energy? Add this to the previous answer
and subtract it from the first answer. What's the non-zero
difference? Now connect a wire. Since both are at the same
potential, I don't have to obfuscate the answer with infinities.
If you object to the proceedure, then you can't use 1/2(CV^2)
anyway, since that result is predicated on bringing charge from
infinity. So, solve the problem AFTER defining your own
reference for 0 potential and AFTER redefining the expression
for the potential energy accordingly.

If you charge a cap and then take one plate to 'infinity', the voltage
becomes infinite. Q = CV: if C drops to zero and Q is conserved....

Hello Folks!

I have a Pyramid model PS-12 power supply which provides 12 amps at 13.5 volts which has no output. This was left to me by my dad when he passed away a couple of years ago.

When I do the tracing with a voltmeter, I find it seems to be working up to the unidentified IC in the circuit used for voltage regulation.

While I do have a schematic, and all other component values and part numbers are listed, there is no info for the IC other than "IC 1." When I look at the IC, it has had the numbers ground off and I have no way of determining the correct replacement for it.

I have scanned the schematic, and can email it to anyone who can assist me with determining a functional replacement.

A search on the web has been fruitless in finding the company address to attempt a followup through them. This is a good little supply that can work perfectly for my 2 meter mobile while in the house if I can get it running again.

Thanks in advance for the help!

If it is a 14 pin DIP, chances are that it is a uA723 voltage regulator. This device has been around for years, and is still used in some new designs. Costs a buck or 2 from any of the standard parts suppliers.

The analogy holds. Assuming lossless caps/cans and wires/pipes,
the charge/water would slosh back forth between the two indefinitely.
The "lost" energy is in the current of charge/water. Of course,
real systems have loss, so that energy quickly becomes heat
and is dissipated.

> The "lost" energy is just due to the same charge being spread
> over a larger volume.

The final system has less energy than the initial system. So regardless of what caused the energy loss, it's still gone from the system, and is lost, not "lost". As you or someone else pointed out, work was done when the capacitors were connected together. This work was done on something besides the capacitors, and that something received the energy represented by that work. And if you want to get the capacitors back to their initial states, you'll have to put that much energy back into the system from somewhere else. With any finite resistance, the work is done on the resistor, which dissipates the received energy as heat. In the zero-resistance case, the result is probably an infinite amount of heat for zero time or some such concoction -- I'll leave that to the philosophers.

==========
Tom, I made a mess of waving the Union Jack.

Yes, Clerk Maxwell was born in 1831 at 14, India Street, Edinburgh.
Died relatively young in 1879.

I assumed Thompson, Lord Kelvin, was a Scot because Kelvin, a name
chosen by himself, is also the name of a tributary which runs into the
river Clyde at Kelvinside, Glasgow where the great man spent some of
his childhood. But in fact he was born in Belfast, Ireland. Kelvin:
1824 - 1901.

Thanks for the correction.

Reg.

Yep. The integral of I^2 * R dt, where I is the current flowing between the capacitors and R is the resistance. If R is zero, then I is infinite, t is zero, and the integral of the product is still finite and equals the missing energy. Look in the index of any circuit analysis text under "impulse". It's easier for me to just put an arbitrarily small resistance between the capacitors and see what happens in the limit as the resistance is further reduced.

No, if you think that is a valid explanation, it is up to *you* to post
the details for others to check.

It's an easy cop-out to say: 'This is my explanation. Now you do the
work of posting the details!'.

I can't help feeling that you would be very quick to express the same
view in another case. Don't you want W. Beatty to post all his
calculations (if any) related to tuned antennas?

>
>73, Bob K6DDX
>

It very well could be the antenna system changing. Back when I was first licensed, I built a (5-band/80-40-20-15-10 meter) trap dipole. Being a student at the time, my financial resources were very limited. Thus, instead of the transmitting style (doorknob) capacitors called for in the plans for the trap, I used ordinary ceramic capacitors (The doorknob capacitors were going for about $25 each, compared to the $.05 for the ceramic ones.). Unfortunately, the ceramic capacitors weren't able to handle the RF energy in the traps, and the SWR would go from 1:1 to about 5:1 in about 30 seconds. Of course, when the transmitter was off, the capacitors would cool down and the SWR would revert to 1:1.

If the antenna in use is a trap style antenna, then I'd check the traps to see if the capacitors could be heating up and changing value (and, it doesn't take too much of a change to detune the traps). 10 watts isn't a lot of power, but if any portion of it at all is being dissipated in the capacitors, it can cause a rather large temperature rise, which can affect the tuning of the traps adversely.

Anyway, it's just another thing to check.

Dave

P.S. Very soon after finding this, I sprung for the doorknob transmitting style capacitors and replaced the capacitors in the trap, which fixed the problem.

P.P.S. Standard Disclaimer: I work for them, but I don't speak for them.

John Woodgate said some stuff about

>No, if you think that is a valid explanation, it is up to *you* to post
>the details for others to check.
>
The details were already posted. If you cant bring yourself to
back up in the thread, I consider putting up the solution just
for you.

>It's an easy cop-out to say: 'This is my explanation. Now you do the
>work of posting the details!'.
>
That would explain why you mention all those nebulous resistances and
inductances without actually showing anything, huh? If you bothered
to read the posts before responding, you might avoid the non-sequiters.

>I can't help feeling that you would be very quick to express the same

I'm sure you cant, but haven't been able to figure out where you
come up with this. Try going backwards (through the thread).

>view in another case. Don't you want W. Beatty to post all his
>calculations (if any) related to tuned antennas?

I think the "if any" about sums up the amount of attention paid to
any of the comments about the antenna. Considering all of the details
(as in the arithmetic, not handwaving) I've already posted showing
exactly what charges flow at what times in the cycle and the uselessness
of the outer plates, yes. I not only expect details, I expect whatever
he considers to be invalid regarding the various expressions I posted
for charges, time constants, voltages and E-fields to be pointed out
along with a reason. Apparently, you not only cant put numbers in this
problem, but you dont even read the posts you criticize.

Subject: ** FLEA at MIT ** Sunday April 16th Cambridge MA
Summary: Buy Sell SWAP Ham Radio Electronics Computers 9AM - 2PM

Spring Has Sprung and the seasons first MIT Flea is only 2 weeks away...

*** !!!! In our Traditional GARAGE and lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday April 16th 2000
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $4 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23-W1BOS/R and W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

Roy Lewallen said some stuff about

>Yep. The integral of I^2 * R dt, where I is the current flowing between
>the capacitors and R is the resistance. If R is zero, then I is
>infinite, t is zero, and the integral of the product is still finite and

I can prove anything I want by tossing in an ifinity and a zero and
blowing off taking proper limits. If I just use tweezers and pick up
the charges and move them the result is the same.

This really doesn't support the claims that physics doesnt provide
physical explanations but instead relies on math (unless you're in
physics, in which case, change "physics" to "most people in physics").
The intuitive, physical description needs none of this, and has the
additional virtue of being correct. The question is more like,
why do people think the first recourse to a physics problem is
all the math they can find?

>equals the missing energy. Look in the index of any circuit analysis
>text under "impulse". It's easier for me to just put an arbitrarily

Now... Expand the step funcnction in terms of the most ugly
hypergeometric functions you can locate in morse and feshbach,
take Laplace transforms term by term, perhaps going slightly
off the real axis and you'll have made this about as difficult
as possible without any particular reason. Why stop halfway?

>small resistance between the capacitors and see what happens in the
>limit as the resistance is further reduced.

Gee. For an arbitrarily small resistance... an arbitrarily small
amount of energy is lost. Skip the resistor and do it charge by
charge. same answer. Guess what. If I take the charge and move
every electrin through a different path through any points in
the universe, I still get the same answer. Where'd all THAT
energy go? If moving charges required circcuit analysis and
resistors, the E-field wouldn't be conservative.

And, for the electrical case, EM radiation. Sound could be the
analogy to EM radiation in the water case.

> > >system from somewhere else.

Let me take a whack at it.

If, as has been suggested, you move the electrons one at
a time by tweezers, and gently pluck them off one plate
and gently place them on the other, then the field does work
on your tweezers as you move the electrons from the charged
plate to the other plate. If you have a sufficiently
clever arraignment of weights and pulleys, you could use
that work to lift some weights. You would have then
stored the energy in a form that you could use to put the
charges back.

Or you could just turn them loose and let them go ballistic,
in which case, just before they hit the destination plate,
they would have kinetic energy equal to the "missing"
potential
energy. They would smack down on the plate and produce heat
and/or light.

Or you could let them trickle through an ordinary positive
valued resister and they would convert the kinetic energy to
heat
and/or light in a sequence of collisions with the resister.

Just picking a mathematical nit:

Although, it is a satisfactory answer for the practical
problem when R is known to be positive and small, if you
let R be negative as you approach zero, you get an
entirely different result. Since the value of the
limit (or even its existence) depends on how R approaches
zero, then we are not allowed to say anything about the
value of this calculation for R = 0. Ultimately,
all we can say is that for R > 0, the result holds.

Sorry, but as a plausibility argument it is fine.

Opinions expressed herein are my own and may not represent those of my employer.

Hello, Lee, on my Pyramid, I replaced mine with an LM-723 regulator, from radio shack.

I bought the matching socket for it...this is very important because you can solder in the socket to the board, and then when the socket is cool, just press in the IC...no heat damage...

Be careful when socketing ICs, particularly linear parts that may dissipate
some heat. Temperature-cycling can weaken the socket contacts until they no
longer make good contact, which causes increased heat in the contact and
results in possibly intermittent failure.

I generally would not socket such a part; they're really not that critical
in terms of heat damage, you're much more likely to damage the PCB if you're
careful.

When I do socket such parts, I'll use the machined-pin Augat type sockets which
seem to have a decent track record with respect to thermal-cycling.

I'm satisfied with this. I lack the curiosity (or time) to try and conclusively determine where the energy goes in an impossible and contrived circumstance. I'm satisfied to know where it goes in any situation that can possibly be constructed. So if the energy does something impossible in an impossible circuit, well, that's ok by me.

In college, I knew a fellow whose masters thesis in mathematics was a 55 page proof that A minus A equals B minus B for any A and any B. He told me that it was relatively simple to prove that A minus A equals zero and B minus B equals zero. The hard part, he said, was proving that the two zeros were equal. This discussion is, to me, similar. I'm really a poor mathematician and even a poorer philosopher, so at this point I'll bow out and leave the discussion to people more interested in these disciplines than I.

This is trivial since by definition 0 is the identity under addition which means 0+a=a+0=a for every single a. Now if there is another identity say 0' then we have:

0+0'=0' with 0 taken as identity

and

0+0'=0 with 0' taken as identity

which means

0=0+0'=0' and the two are really one and the same.

What is this guy doing these days?- in sales.

You might find it easier/less real estate to use an LM3524 or LM3525 Both NatSemi and Siemens have designs on their websites. Remember to use ferrite beads for RFI - the switching transients - aren't nice.

I don't know the correct answer, but might it not be easier still to forget about generating a symmetrical a.c. signal for the transformer, and instead run a pumped inductor switchmode supply, into the filter section of the original supply (after the rectifier.)?

Your asking that question aroused my curiosity, so I did a quick web search for his name. I hadn't seen or heard from him since I left Illinois Institute of Technology in 1964. At that time he was working toward his Ph.D. Apparently he's no longer with us, but a scholarship has been established in his name. The brief bio is reproduced below.

Since your proof is so much more elegant than his was, they're sure to name a scholarship after you, too.

Roy Lewallen, W7EL

THE JAMES W. PETTICREW MATHEMATICS SCHOLARSHIP

The James W. Petticrew Scholarship was established in March of 1994 by a group of relatives and friends of Dr. Petticrew, who was born in Springfield,
Ohio on December 26, 1940 and obtained his Ph.D. in 1969 at the Illinois

Institute of Technology. He worked in public schools and colleges in Indiana
and Illinois before coming to the University of Texas-Pan American in 1985.

Dr. Petticrewï¿½s main interest in mathematics was geometry, and during six years at the University of Texas-Pan American he produced several papers
and made numerous presentations in collaboration with other faculty in the Department. Another strong interest of his was computer literacy, which he
taught on a regular basis.

Dr. Petticrewï¿½s passion was to collect books, most of them in the area of mathematics. One of the most remarkable characteristics of his personality is
how quickly and deeply he fell in love with the Rio Grande Valley and its people, even though he had lived most of his life in Indiana and Illinois. When
writing his will, Dr. Petticrew's main concerns were to make sure that all his books were donated to the University of Texas-Pan American and that an
endowed scholarship was established with some of his estate. His relatives and friends made sure that this was done for the benefit of UT-PA
mathematics students.

Dave,

The antenna ia a simple dipole with a close-to-resonant 10M
segment and a not-too-resonant 40M section on a common center. The
40M has capacity hats for 15M. The capacity hats are figure "8"s of
wire, out at the 15M 1/4 wave position. The feedline is RG-8 with a
10' section of RG-8U in a 10" multi-turn loop as a balun. There just
isn't all that much there between the transceiver and the ionosphere.
I suspect the SWR meter and will do a comparison test.

You asked what he was doing these days, and I answered as well as I could.

I didn't read or even see his thesis. What I posted was the way he described it to me. So either 1. He lied to me; 2. I lied to you; 3. I misunderstood what he told me; or 4. Perhaps you don't know quite as much about the subtleties of one particular area of math as he did. Take your choice. I don't pretend to even begin to understand the subtleties of number theory, but I have every reason to believe he was telling me the truth, and his explanation didn't leave much room for misunderstanding, so I'll remain convinced that he did what he said. You'll remain convinced that he didn't, and that's fine. Like you, I don't have any problem dealing with subtraction and zero, but I also know that within the careful structures of number theory, the conventional definitions we accept and use don't necessarily apply. But in no way am I capable of providing any proof or elaboration beyond what I posted.

I was simply trying to make a point, not start a pissing contest.

Now, I'd like to disengage from this tar baby. Carry on.

Hmm,

So when we take a limit as N->infinity we must also come from
the other side? So we don't know that the taylor series expansion
of sine or cosine actually converges?

There are good reasons to exclude phenomena that add energy
to the system. Doesn't a negative resistance imply this?

It is not clear to me for example what potential a electron has
at distance 0. And I certainly have no idea what the potential
is at negative distances. But I don't feel bad about approaching
the result by doing calculations for small positive distances.

Chuck

That's why we avoid infinity.

Actually sine(x) has no limit as x approaches infinity.

The point is a mathematical one, that if t= function
is continuous, then the the limit is the same
regardless of which way you approach. The particular
function at hand did not have this property at zero,
so you really don't get to say anything about what happens
at zero, based only on the one sided limit.

But you know what I mean.

The potential at infinity by definition is taken to be 0. Q is
conserved. You do not need to move the plate anywhere, I just
figured it would be easier for you to deal with than moving
charges from infinity. Which is how the potential at a finite
distance is defined. I'll resort to the pedantically correct
argument so that I dont casually ignore the fact that the potential
energy is due to the conductor holding the charges which are
moved from infinity to the conductor. I have a conductor at
0 potential (with the refernce point 0 at oo). I can move 1
electron at a time to the plate. Without a wire. What is the
work done?

You can still bring in the plate from infinity. It takes the same
work to assemble the charges regardless of where you do it. Moving
the first charge to its final location is always a freebie. Once
the charges have been assempled on the conductor, relocating
the conductor doesnt cost anything. It moves as a single charge.

2815. IC746 AM Audio Mods

Anyone brave enough to have tried to get into the modulator of one of these rigs to clean up the AM TX?

You can get about 60% on mine without too much distortion, but after that it gets pretty harsh sounding and various forms of distortion are visible on the scope.

Outboard audio with and EQ helps, but it is limited.

The work wasn't done on the capacitors. It's done on the charges.

> and that something received the energy
>represented by that work.

It goes into the potential energy stored in the field.
With one charge at infinity and another at the origin,
there is, by definition, no energy stored in the field
(but feel free to pick any value, since it drops out
of any calculation). Moving the charge to some distance
r fron the charge at the origin requires work to be done
against the electromagnetic force (just like changing
the height of an object in a gravitational field). The
work done is the potential energy stored in the field.

> And if you want to get the capacitors back to
>their initial states, you'll have to put that much energy back into the
>system from somewhere else.

Yep.

> With any finite resistance, the work is done
>on the resistor, which dissipates the received energy as heat. In the

Nope. The the final configuration can be acheived by moving the
charges along any path to yield the same answer. Your choice for
a resistor as a means to dissipate the energy cant support that.
You get the same answer whether the wire is 1 cm long or arbitrarily
long. A resistor isn't conservative. This is. The work done is
manifest in the change in energy stored in the field. If all of
the charges are further apart, the forces on them are lower.
It takes less energy to hold them in place. (work isnt always
negative or a loss -- when you lower box from a shelf to the floor,
you do work in lowering the boxes potential energy).

>zero-resistance case, the result is probably an infinite amount of heat
>for zero time or some such concoction -- I'll leave that to the
>philosophers.

Where I come from, the energy stored in the field in the capacitor is 1/2 * C * V^2. Using this simple calculation, the sum of the energy in the two capacitors is less than it was when we started. But you're saying it's still there someplace, so there's energy in a field somewhere other than the capacitors. Where is this field?

If all the initial energy is still in the system, as you say, you should be able to use it to get the capacitors back to their initial states of charge without application of an external source of energy. Please relate how you'd do this.

The same way you get the energy back after lowering a box. You do
work to lift it. After the charges move to a lower potential, you
do work to put them back. Where I come from there's a such thing
as potential energy. Why dont you try what I suggested the first
time before continuing to ask the same question. Start with two equal
capacitors and bring in charge q. Then just use 1 capacitor and
repeat with 2q. Now, post the result and explain exactly why the
energy is different. I dont see how to simplify it further without
just referring to an introductory physics text like halliday &
resnick or sears, zemansky & young and reading through a better
explanation than I'll probably provide. Is there some objection
to breaking out a pen and paper and perhaps a book to check and
see what what written about it before last week? It's one thing
to not know the answer, but quite another to not check one
before insisting too many times that a solution posted is wrong,
when, if nothing else get's the right answer without customizing
the problem with features to make your alternative work, if you
dont ask too many questions about the less rigorous parts.
I believe the person posting the correct answer did so on
the third or fourth followup. Try checking it.

Looking for 19" steel equipment racks, height from 4' to 7', depth min. of 22" with rear door.

Prefer rack not beat up or full of holes.

Will pick up within the state of Florida or close by!

Please e-mail me with details or PIXs

TNX & 73.

Go to SkyCraft Parts -- surplus electronics in Orlando (Winter Park)
On the corner of I-4 and Fairbanks.

Have your choice there (course it cost $$) but a very interesting surplus
electronics store.

cheers

Hello, thanks for the added input in the matter. I used the type of socket
that was specified to work with the 723 chip... Do you think I should take the
socket out and resolder the chip to the board? So far I have had no problem
with it. Maybe I got lucky?
I was trying to be helpful, I hope I didn't cause a problem.

That's why I stick to tubes ! :o)
Kind regards, Joe Pratt

2827. Re: "HELP!" Tube info (4-400) (4-500)

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-04 00:00:00 UTC
From: tubecntral@aol.com
Message-ID: <20000404144403.02630.00002427@ng-cg1.aol.com>
Source record: 61652

Hello, Lou, you asked:

>information about tubes. First of all, What is the difference (if any)
>between
>a 4-400 and a
>4-400A?

4-400 run like this:
4-400A is the equivalent of a 8438, which is a transmitting triode, Thoriated Tungsten (TT) filiment, 5.0 V @ 14.5 amps. Rated at 400 wats up to 110 Mhz.
T
here is no difference in Sibley's 'Tube Lore' for 4-400A and 4-400... BUT

The 4-400-C is an update of the 400-A, also known as a 6775, which is the same as a 8438, but the 'C' has smaller plate structure, lower operating temp. filiment, one-piece plate cap, and basically ruggedized for longer life.

Lou also asked:
Secondly, I need info on a 4-500, is it the same as a 4-400 but just
>newer and higher plate dissapation? Is the tube socket and filament
>requirements the same as a 4-400?

I see no listing for a 4-500, perhaps you had it confused with a 3-500Z, or the 4-400C like described above.

Best of luck, I hope this helps you a little bit.

The source for this info was 'Tube Lore', by Ludwell Sibley.

While I am on the subject, I have a good 4-400C, tests 85%, was to be used as a backup in a radio station transmitter, it's anybody's for 55.00 shipped in USA.
I believe it's an Eimac or Amperex.

Regards,
Joe Pratt, Tubecntral@aol.com

problem
> with it. Maybe I got lucky?

The problem is not that the socket does not match the chip; any
14-pin DIP will "work" in any 14-pin DIP socket. The issue is
of long-term reliability; the 723 chip can and probably does
dissipate some heat under normal operation (the amount of heat
given off will vary with respect to the load on the power
supply; even though the 723 drives external pass transistors,
increased load on the pass transistors results in increased
load on the 723).

When the 723 heats up and cools down, it may eventually weaken
the contacts on the socket, by taking out the springiness. When
that happens, the contact itself will heat up and soon after
become unreliable. Most of the inexpensive 14-pin sockets with
the thin tin-plated leads can't handle much heat; the more expensive
sockets with round brass pins have proven better in my experience.

So, to answer your question, I'd say do nothing for the moment,
and if the power supply becomes flakey down the road, one of the
first things you should look at is the socket.

2842. Engine driven DC Power Supply?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-04 00:00:00 UTC
From: CessnaPilot <stinson108@my-deja.com>
Message-ID: <8cduh8$4i6$1@nnrp1.deja.com>
Source record: 61667

Okay, here's the deal: Shack has no AC source and is far from any so it runs off batteries and solar panel. I decided to try to activate an old tube rig that draws 22 amps which would deplete the batteries in short order. So... I went to the local flea market and came home with a 4 HP lawn mower engine and a Ford alternator. The alternator has a built-in regulator. The idea is to kick in the 35 DC amps when running the old tube rig. My first concern is being able to hear a weak DX over the noise of the engine. I can move it a couple hundred feet from the shack, but don't know if the voltage drop would be a problem. Have you or your friends ever tried or done this? Any suggestions or comments? It sounds like a good idea to me, but then so did some other things I've tried that I won't be doing again. All opinions respected. TNX, Stinson

I also find that sometimes a "snap on" choke with a couple turns of transmission cable works to choke
off currents on the coaxial cable outer conductor. This has worked for me when all else failed.

Roy McCammon said some stuff about

>If, as has been suggested, you move the electrons one at
>a time by tweezers, and gently pluck them off one plate
>and gently place them on the other, then the field does work
>on your tweezers as you move the electrons from the charged
>plate to the other plate. If you have a sufficiently
>clever arraignment of weights and pulleys, you could use
>that work to lift some weights. You would have then
>stored the energy in a form that you could use to put the
>charges back.

Since the E-field is conservative, the wights and pullleys
don't need to be arranged very cleverly at all. Any friction
involved is additional energy you have to provide.
>
>Or you could just turn them loose and let them go ballistic,
>in which case, just before they hit the destination plate,
>they would have kinetic energy equal to the "missing"
>potential
>energy. They would smack down on the plate and produce heat
>and/or light.
>
But the assumptions didn't involve elctrodynamics (neither do
the assumptions in most circuitry).

>Or you could let them trickle through an ordinary positive
>valued resister and they would convert the kinetic energy to
>heat
>and/or light in a sequence of collisions with the resister.
>

Then the energy to move the same charge back through
the resistor to restor the original configuration would
cost you again. But the field is conservative and the
any energy going one direction has to be recovered going
back.

>analogy to EM radiation in the water case.
>
>

The analogy fails to be precise because the forces are different.
In te water example the only force is gravity and the result
is a system which is stable against perturbations, so it can
oscillate about the potential minimum. The electric field due
to a system of charges is not a stable system. The potential that
provides stability (as in why charges stay on conductors) is
the magnetic field in the conductor. So 10 charges on a conductor
move as far apart as possible. Any oscillations will occur about
the final locations of each individual charge.

The old vibrator just produce a square wave using mechanical switching. I am not trying to better that by very much. Neither am I trying to modify the existing circuit to any great deal. I just want something that will replace the vibrator. Plan is to first build something that will work on an external box that has a cable and plug Ican plug into the old viberator socket.Next paln is to put it on a chassis that will plug into the place left by the vibrator.

2851. P channel FETs.

I am NOT a licensed electrician, but had studied for the E2 test.

I believe a small building would have a Sub Panel and not just a 120v feed.

How are you feeding the building, UF cable, conduit (metal or plastic)?

A short piece of metal conduit (grounded) around the feed to the building will act like a choke and bounce a lightning hit back in the direction it came from basically isolating it from going in or out. I saw this used in the 13,800v power ducts for building feeds, helps save the transformers from hits during storms. I have seen it also used on antenna lines at the entrance to buildings.

If you have the NEC, check the section on antenna's and sub panels, might help you decide what you want to do.

I think you may be making it more complicated than necessary. Don't ask
me to find it, but back in 1964 or so Popular Electronics had a construction
article on building a vibrator replacement. It wasn't much more than
a couple of power transistors and resistors, and they built it into a can
that originally housed a vibrator. I'm sure I've seen similar schemes
elsewhere, though I can't point you to anywhere at the moment.

This isn't really a surprise since there were plenty of inverter power
supplies using transistors that were basically the same idea.

The Radiotron Designer's Handbook that has a section on vibrators
says they normally ran at about 100 to 120, they were cycles back then
not Herz, but I have no idea whether that was standard or not.

Yes there are "P" channel FETs, but you seldom see them in hobby circles.
Older magazines seemed to show them more frequently.

That said, I sure can't supply you with a complement to the MPF-102 or
some other matched set. I just looked through some data books, and I
saw nothing that showed pairs in that fashion.

So it's a matter of going through lists of FETs and trying to find
some that match up.

OK -

The LM3524 and LM3525 have the gates you need to drive a HexFet - need only a resistor and capacitor to control duty cycle and timing, and they are cheap.

Michael has the best route to follow. Remember, most transformers can be used a higher frequency within reason and it will run more efficiently. Look at a lot of old HP equipment. Most was designed to support 50 - 400 Hz. 80 to 120Hz should be fine. Also the filter circuits will be more effect at the higher frequency. Let me know if you start marketing something, I might be interested in a Mallory 1501 replacement. A very popular 6/12V 4 pin vibrator.

> at zero, based only on the one sided limit.

Absolutely, and a good point. I often get in at the
end of these things because I'll read your posts because
I can't keep up with the general volume. But ISTM
that you took it too far in service of your point. If
we actually were doing this for theoretical reasons
probably the ratio of L and R would have to be
constrained as we let both or one tend to zero. But likely
there would be some physical basis for it. In a super conductor
R can go to zero but L would not and we would get a sensible
answer. As you point out transient times will become important
too; one has to think what R=0 means. Does it mean V/R
is infinite or does it mean that I^2R is 0??? My first
inclination is the latter, and to think of V/R as a limiting
case for low frequencies and low currents.

>
> But you know what I mean.

Yeah, I apologize, but you know one sided limits are used
a lot in very rigorous ways.

But in the context of this thread information like that is
like giving Ghengis Khan nuclear weapons. Soooo easy
to misuse as you point out. They really do make it much
easier to invent perpetual motion machines. As above
V/R -> infinity, I^2R -> 0, L = constant. L/R = constant,
or if we think about leakage across very large caps
area-> infinity, C-> infinity, R->0, will give a wide variety
of phenomena. Mix any two at random and you can prove
just about anything. For that reason I'll just duck out now.

So I think I've gone and proved your point. The limit doesn't
say much about R=0 unless you specify more.

Chuck

Dana is right on the money on this. Either use a good socket or solder it in directly.
BTW: I replaced the IC in my Pyramid 30 amp supply with a 723.

i have a cb radio someone gave and want to convert to 10 meters...did not have any recieve and found broken lead to so-239...recive ok now but no transmit suspect that maybe they keyed into open and blew final...can i test the transistor without removing it from the rig...its a 2cs2078 in a 220 case

2865. Homebrew thermo-controller?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-05 00:00:00 UTC
From: aj <ahall@uiuc.edu>
Message-ID: <ahall-FBCD38.15271405042000@news.cso.uiuc.edu>
Source record: 61545

Hello everyone,

This is not a radio question, but since we're all home-brewers here, I was wondering if you guys had any thoughts on how to make a thermal-controller for the lab.

The way a thermal controller generally works... it monitors the voltage signal from a type K thermocouple (voltage is directly related to temperature), and turns on or off an AC plug (which a heating element is plugged into... no need to change the voltage or power).

So, basically, we need the ability to set the desired temperature (voltage to compare the thermo-couple to), and the ability to turn on and off the heating element... on if the voltage is less, off if the voltage is more than desired.

These things are a pretty penny in the lab-catalogues... but then again, most of that stuff is ramped up in price anyways because they usually sell to institutions.

The application seems relatively simple, but I'm not a great electrician... any thoughts on this?

Please e-mail me your replies. I'll try and keep up with the news-group, but I'd hate to miss your reply!

Thanks a ton!

-Allen Hall (n9rzc)
n9rzc@uiuc.edu

ps- again, sorry for the non-radio question... but I figured who better to ask than my ham pals!!

2866. Microwave homebrewing

Howdy, all -

I have a couple old X/K radar detectors that I'd like to
use in microwave experiments. Some questions for the
knowlegable among you:

- What's the best (cheap) way to adjust the frequency?
Is there an inexpensive microwave freq counter, or perhaps
a clever device I can build?

- What is the legality of using a radar detector without
readjusting the frequency? They apparently radiate RF
even in their original application, so are they then
Part-15 compliant? or licensed somehow?

I'd love to hear any success stories out there. I've found
many of the web sites related to microwave ops, but some
email exchanges with experienced microwave homebrewers would
be appreciated.

That the output power diminishes with decreasing battery voltage, is entirely reasonable. As a case in point, look at the Yaesu FT-50 handy talkie. To obtain the full 5 watts output, you must use one of the batteries that provides 9.6 volts. Lower voltage batteries = lower output power.
Personally, I would favor adding a cell to increase voltage than to use resistance to decrease it, thereby consuming more power. The batteries we used in the 1950's had lead straps across the top that connected the cells. You could drill into any of these straps, insert a self-tapping screw and come up with about any voltage you wanted. These new batteries are made a lot cheaper now and I don't believe there is a strap to drill into. I don't know how they connect the cells in these.... might bust the case off a dead one and take a look see. 73

To avoid voltage spikes when keying the rig, I believe I would just run off the batteries. If they got too low, shut down the station while your 35 amps built the power back up. I don't know how you would know when the charging was complete, but there must be something at Auto Zone that would check the amount of charge in the batteries. That would be a lot safer for the components in your transeiver and a lot quieter while you were copying DX. 73 Guy

A reserve is the price, chosen by the seller, below which either the seller or the buyer can opt out of the transaction. It's generally not disclosed -- when you bid on a reserve auction, you don't know if a bid of a given amount will meet the reserve until you actually bid.

Personally, I don't like reserves and don't see the point in using them. I always set a reasonable minimum bid and let the market do what it wants.

I know you tend to get a bit casual in the US with your 117volt outlets, but
please don't even think about doing it according to your suggestions!
Ther are many sources of suitable transformers. Some suggestions-
Old electric blanket controllers (low voltage type).
Old Stereo amplifier transformers (these are most likely in the right area of
output voltage).
Quartz halogen lighting tansformers. These are common these days and run from
12 volts to 48 volts output.
Any supply using a non polarised plug, even with only 117 volts is an accident
waiting to happen. Don't forget anything hooked up to the circuits from the
relay units can also
energised unless the supply is totally isolated.

Thanks, Michael:
It is good then to know that the P channel FETs are out there yet? Instead of using a proposed "differential amp." for a balanced input RF amp. and the resultant output coupling problems, why couldn't I use a "complementary pair" of N and P type FETs instead? Wouldn't this configuration yield a "common source" output connection for a simpler method of R/C coupling into a single-ended, emitter follower or what-not?

Since you are talking about antenna switching, I assume the relays are outside and thus, any leakage can be very hazardous.

>Can I use a
>combination of resistors and some diodes to get some crude dc from the
>110v ac enought to power 1 relay at a time.

If everything is inside in a dry environment in a well isolated box (which is questionable in the case of an antenna switcher :-), some low current power supplies could be constructed using capacitors as the current limiting element (both in the live and neutral connection), thus, avoiding the huge power dissipation due to a series resistor. A 1 uF capacitor will have a reactance about 2700 ohms at 60 Hz, thus, maybe 10-20 mA of useful current could be extracted (due to two 1 uF capacitors in series, one in the live connection and one in the neutral connection, thus not needing a polarised plug). A bridge rectifier and a small filter capacitor would also be needed to power the relay. The application would be floating around 60 Vac, thus all external connections would require opto isolators, transformers or relays.

This trick is useful for powering some stand-alone CMOS timers or other very low power devices, in which the series capacitance could be down in the 10 - 100 nF area and even with an isolation fault in the box, the leakage current would be limited to a few mA due to the reactance of the capacitor.

However, I would not recommend such practice for an antenna switcher, especially if the device is used outside due to safety reasons. There would also be problems of how to activate the relays, since the relay supply would be floating. Finding 100 - 1000 nF capacitors with required AC voltage ratings will be hard and their size would be larger and price would definitely be higher than a cheap transformer.

While it may be problematic to find cheap transformers directly suitable for 48 V, there are a lot of wall warts that give out either 16 Vac or 24 Vac and with a suitable doubler or tripler, the voltage can be increased to 48 Vdc.

I'm going to use it for BPSK demodulation, but maybe it's better to
cascade
a LP with a HP (using two op amps, 2x2 resitors and 2x2 capacitors)? The
problem is that I want to be able to change the received frequency in a
simple way; can the BP filter be syncronized with the local oscillator?

>Before you buy.

Theoretically, it'll work, but there are some design considerations that
you should take into account. Yes, the gasoline engine will be noisy.
However, with a suitable muffler, that noise can be minimized. Don't
settle for the tiny muffler that are typically installed, but, instead,
go for a larger muffler with better sound deadening construction. Also,
pay attention to the orientation of the muffler. But, what ever you do,
make absolutely sure that the exhaust if vented well away from you. Not
only is Carbon Monoxide posioning no fun, it is deadly!

One approach that might be worth considering is to use a sound shield between
the generator and your operating position. Just a piece of wood can divert
a significant amount of sound energy. Also, consider shrubs or trees, too
(but, don't let the exhaust poison them). However, don't let the sound
shield restrict the ventilation and cooling for the engine.

There should be a body of literature available concerning such installations,
since quite a few people use generators for emergency supplies. And, when
you consider the number that use generators for the Field Day exercise, someone
has surely tried this.

It will require some very heavy cables to conduct the 35 amps without an
appreciable voltage drop (and, I assume that you are dealing with a 12
volt source, so you haven't got much voltage to spare). The obvious
approach is to determine how much drop you can tolerate, then find out
what resistance you can tolerate with 35 amps flowing. Finally, use a
chart of cable sizes versus resistance to find how big of cables you'll
need (And, don't forget to account for the drop in both sides.). My

guess is that you'll find that you want to keep the run fairly short.

An added consideration is that you may want to consider the inductance of the cables. Two parallel conductors won't have much inductance (especially if they're run close to each other so the magnetic fields cancel), but, if you're switching 35 amps, and are only dealing with 12 volts, a small amount of inductance can result in some fairly large voltage swings. Make sure that the keying of the transmitter doesn't result in voltage spikes large enough to fry a component (I'm told that the inductive surge caused by operating the starter in a car can result in 80+ volt surges on the 12 volt system.).

I assume that RCA doesn't have a museum and wouldn't be interested
in the materials, would they?

You could try to find a museum which specializes in electronic
devices, or, even more appropriately, vaccum tubes. I've seen some
sites on the web, but I don't recall the address (although a quick
search should come up with a few). Most of these are small, but I'm
sure that some would appreciate a donation of some of the materials.

You might also drop a note to the ARRL (www.arrl.org) to see if they
might be interested in some of the material for their museum.

You could also scan (some of) them and post them on the web. I'm
sure there are quite a few people who would be interested in reading
them.

Or, you could try to auction the stuff on e-bay.

FS quantity 4 Varian vzj2700d4 3kw klystron hpa's. complete and operational with solid state ipa's and 80 dB of gain. wr-137 input and output. 20 dB manual attenuator. 208 volts three phase. Full metering: beam voltage, beam current, body current, reflected power, forward power (4000 watts), drive power, filament volts and current, beam and filament hours. Many spares including klystrons,
filament and beam transformers, 3 phase autotransformers, meters, wiring harnesses, and more.
These amps have either 12 or 24 channel tubes and will make >3kw across any 40 mHz. bandwidth.
Higher power outputs are easily obtainable with reduced bandwidth tuning of the klystron. The tube is a Varian va936 series, 5 cavity. Typical operating parameters are 8kv@1 amp with PO about 3 kw. I
have operated the amps at 8.5kv with output near 4kw. The beam power supply is variable from about 4 kv up to about 10 kv. The amp has arc detection and shutdown, as well as an output isolator.
For more specific information please e-mail or phone. SERIOUS INQUIRES ONLY! THESE ARE NOT TOYS!

15 minute epoxy works fine for this. Wax the screws then put the epoxy inthe
holes and go ahead and put the screws in with the circuit board out. When it
sets take the screws out and mount the board. No drilling required

The 4-500A has a 10v, 10.2a filament. Max. ratings are 450mA at 4000v.
Max screen potential is 1000v. The constant curves indicate that the
450mA rating is probably conservative for SSB service. .

Source record: 61689

A solution that can be used to boost the 12 volts supply to higher levels is to use an isolated 12 Volts in 5 Volts out DC-DC converter with voltage feed back.

The input of the converter across the battery contacts and the output of the converter in series with the positive borne of the battery (the negative side of the converter), taking the output voltage from the negative side of the battery and the positive side of the DC converter.

The voltage feedback has to be changed (the negative side to battery ground) and the resistor values adjusted to give the output voltage you need.

I have used this arrangement to maintain 13 Volts out with decreasing battery voltage which can be as low as 9.5 volts battery voltage.

If I remember right VICOR has several Bricks DC converters that can be used for that purpose (the one I used were my own design)

Remove the transistor and use a multi-meter to check the
diode junctions from emitter to base and from base to
collector. Looking at the front of the transistor with the
leads pointing towards you, the connections are:

1 Base
2 Collector (Heat Sink Tab)
3 Emitter

You would do best with a ceramic insulated rotary switch. The ceramic is low loss and has a high dielectric strength. Low capacitance across contacts. Get one with substantial contacts, as you will be carrying considerable current.

And of course, never hot switch an antenna switch or you may damage the switch and your transmitter.

Some alternators have an extra voltage sense wire. With one of these, you can run
the sense wire back to the shack where your batteries are, compensating for any and
all voltage drop from the alternator. I had a lucas alternator (with inbuilt regulator)
in a mini that had this extra wire.

The easy way to do this is with a PIC, even easier still with a Stamp I, Stamp II or BX-24 which program in readily understandable languages.

Monitor the voltage with an ADC - I use serial devices since they take fewer pins.

Turn the heat on or off with a relay, or you can use an optocoupler (MOC3010) and a triac (MAC8 or any of the husky ones from Motorola, etc.)

Have you already searched at the book "Digital PLL Frequency
Synthesizers - Theory and Design", of Ulrich L. Rhode, DJ2LR/KA2WEU ?
It has many examples of very low sideband noise crystal oscillators.

--> An automotive ammeter, between the batteries and alternator, would be of some help. With the load switched off, if there's current flowing into the batteries, they're being charged. No or very low current, they're basically full. A remote shunt ammeter would allow the meter to be placed in a visible location without adding to the high-current wiring length.

Charge in lead-acid batteries can also be checked with a voltmeter, but that'd require shutting off the alternator (and solar charger) and letting the voltage stabilize, for a really good indication. The voltage sag under the load from the tube rig might be a good indication of state of charge, though.

The third method is to use a specific gravity tester (a few bucks at any auto parts store), but that's probably not very convenient for your purposes.

I have the following 2 amateur radios for sale:

Yaesu FT990AC, internal atu, 500/2.0k/2.4k filters fitted, vgc, sp6 speaker, both boxed, with manuals £800

Yaesu FT726R, 2m/70cm/hf/satellite modules fitted, desk microphone, fairly good condition, boxed with manuals £400

Lack of interest and job, forces reluctant sale.
Must sell....
Any questions, send to:

Stuart - G0GNM

Notch for what frequency? How deep a notch do you need? How small an attenuation do you need at certain other freqs? How much power do you need to handle? Passive or active?

Cheers,
Tom

Source record: 61573

If you want to make one yourself, a simple notch filter can be placed in the IF amplifier at 9 Mhz or 455 kHz.

It consists of a series-resonant quartz crystal, approximately resonant at the LF end of the IF bandwidth, immediately in parallel with the input to the transistor in the first stage of the IF amplifier. This is usually the 1st gate of a dual-gate FET.

The crystal is placed in series with a tuning capacitance, a capacitance diode about 40 pF. The notch frequency is adjusted by varying the DC diode bias. A potentiometer on the receiver front panel provides the DC control volts.

Switch the filter out of use with a high reverse bias voltage on the diode.

Copy the circuit of a modern Icom receiver or transceiver.

No it isn't. Do the math--R cancels out and the energy lost in the
resistance is a constant one half of the initial energy. That's what Roy
and Reg have been trying to tell you.

There's no need for smoke and mirrors and arm waving and quantum corrections
when doing a simple circuits problem. And there's no conflict between
circuit analysis and physics. If you want to make the problem harder, go
ahead. But please abide by conservation of energy. Half is still in the
two capacitors and half heated the resistance--however small.

Hello Morgan

Using xtal ladder circuits - it is often easier to produce a narrow CW filter than trying to get the xtals to broadband up to say 3Khz at the 3dB points. For the narrower filter - you do need to have sufficient "Q" in each xtal to begin with.

Best of luck ... Ken

Are you sure of that? Oil-filled capacitors were commonly filled with PCB-containing oil, but I didn't think electrolytics ever were. The stuff is definitely caustic, though.

Tektronix used to clean older scopes with detergent and water but that was before the days of IC sockets and surface-mount switches. There's detailed information about washing old scopes in "Oscilloscopes: Selecting and Restoring a Classic" by Stan Griffiths, W7NI. It's self-published, so you can probably get a copy directly from Stan, w7ni@teleport.com.

seems what you really need is an audio filter to improve the
selectivity, I have good experience in using the TimeWave DSP-9 with
selectable 100, 200 and 500Hz CW bandwidths.

DSP-9 was available as secondhand at very low price because everybody
seems to be looking for new blackboxes with all sorts of facilities
you never need. W9GR DSP is another similar construction.

Use it with several different receivers including some boatanchors, on
80, 40, 30, 20m and VHF/UHF, might even work for 15m.....

The AD9852 has a built-in PLL multiplier(4X to 20X) for the 300 MHz
clock. Perhaps you could swap your AD9854s. 8-)

ADI has an app. note. for the AD9850 with details of a 150 MHz clock
circuit. You could put the output into a doubler.

Wavetec type LC filters

Model B2, #of section, center freq, band pass, average power

6 450 mhz 40 10 watts
5 50 5 10
4 400 40 10

The other letters have to do with connectors I believe. This was taken
from 1981/1982 Wavetec catalog. The information is rather sketchy but this
is all I have.

I have a similar project where I want to switch coax between two antennas in the car (a 2m/440 vertical for 2m FM and a loop for 2m SSB with 50W max). My design goal is to use a relay so that I can have a BASIC Stamp read the band/mode data from the rig and trip the relay as appropriate. Any suggestions for relay types and what the dB loss in the relay might be? I'm not doing any 440 SSB from the car so the relay would always connect to the vertical for UHF.

You may want to investigate using a Dowkey relay. These have a
reputation for high reliability, low loss, low cross-talk, and are
specifically designed for VHF/UHF RF and microwave applications.
Plus, their web-site offers excellent technical information. But,
be warned that they aren't cheap. The web-site is:

http://www.dowkey.com

It may be possible to use another relay. But, the problem will be
that, unless the relay you choose is designed for UHF applications,
it may have an unacceptably high insertion loss, or may result in a
high SWR condition. It doesn't take much inductance or capacitance
to really mess things up on the 440MHz band.

Dave

P.S. Standard Disclaimer: I work for them, but I don't speak for

I am currently in the desing phase of a low noise xtal oscillator at
60 MHz. I will try a MMIC and use anti parallell diodes for limiting.
This has been tested in VHF Comm magazine and produced stunning
results. It is very easy to simulate in a linear simulator as it uses
50 ohm termination. I was truly amazed of the published performance.
If I succede with the design I will let you know!!!

Cheers

I have 2 of the type M67712 class AB 30 Watts out average, 40 Watts max. The input drive is 300 mW. I am asking $ 60.00 each for them. RF parts wants around $80.00 for the same.

These are brand new never been used and still have the one inch leads on them.

Thank You,

2941. Re: .2Mhz notch filter for FM Broadcast band

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-07 00:00:00 UTC
From: Tom Bruhns <tom_bruhns@agilent.com>
Message-ID: <38EE6F9C.DA39F966@agilent.com>
Source record: 61593

You might be better off turning the beam to null the strong adjacent frequency signal than to try to notch it. That's asking quite a lot of a filter. Notching 101.7 by 40dB relative to 101.5 looks to me like it would take a single coaxial resonator about 6" diameter. Multiple resonators could do better, but in any event that spacing is half the percentage that repeaters on 2 meters usually use. -- Or, get a receiver with very good adjacent channel performance. (Is it really adjacent [+/- 0.2MHz] or alternate [+/- 0.4MHz] channel?) Also, AFAIK FM broadcast stations do nothing special to attenuate their out-of-band sidebands beyond what just comes out of proper FM modulation, so a local station may ligitimately have significant energy in the adjacent channel. Again, a directional notch will be much more effective than a spectral notch in that case.

Cheers,
Tom

>

I didn't clarify - the black stuff was caused by FLAMES that emitted from the failed cap. It was small - 100 uF 20V - in a Tek 214 scope - (mid 1980s era at the earlist). I replaced the cap and the scope continues to work - I just think the carbon (black) stuff should be removed as there are probably impedance paths that should not be there now. Fortunately the trouble was in a low-voltage area (just the main "bypass" cap in the DC/DC inverter).

Of the various suggestions here I think the isopropyl alcohol cleaning sounds most useful.

You are right but when talking about internal (junction) temperatures.
I'm talking about external (case) temperatures. Higher power transistors
normally have better heat junction-to-case transfer; so, for the same
junction temperature, more heat is transferred to the case. As this is a
better radiator than a smaller transistor, the overall system will
withstand a higher output power.

If the capacitor did have some PCBs in it , there would not be enough
there to harm anyone unless he might lick it off the board. PCBs are
not harmful to the skin in small ammounts. They are only toxic when
they get into the food chain.
For some reason many think that the PCBs are like a deadly poison.

I own an IC-746, which also has a useless "tune" control on the front panel
and a very similar-looking 4 pin molex connector on the back.

Does anyone know if this circuit will also place the 746 in a low-power tune
mode for 10 seconds? This would be great for both antenna tuner and amp
tuning.

Freon won't hurt most plastics, but acetone attacks lots of them. I wouldn't use acetone, MEK, or similar solvents if I were you. Isopropyl alcohol should be fine. Or if you're not cleaning too large an area and need a little stronger solvent, naphtha might work and it won't harm most plastics. But be careful using it -- it's obviously very flammable, since it's sold as Coleman fuel and cigarette lighter fluid.

>Any suggestions on how to clean up the black gunk?

My first suggestion would be water and a toothbrush. This will do it if it is just electrolyte. If it is carbon there is no suitable solvent so you'll just have to let it dry and try to brush it off.

If you use water, follow up with an alcohol rinse, and be careful of what you get wet. Keep water out of transformers and pots, and anywhere else it could sit and cause corrosion instead of drying quickly.

Make SURE it is dry before powering up again.

Dear All list members,

Can anyone help me locate the companies listed in the 30th Edition of the ARRL Radio Amateurs Handbook published in 1953? I would like their Last Known Addresses, Current Address, Phone Numbers, website addresses, subsidierys, etc. and any other useful information. Please submit any information you can provide to
gbowne@email.msn.com

The companies (as listed in the 1953 index) are:

Advance Electric & Relay Co.
Allied Radio Corp.
American Lava Corp.
American Phenolic Corp.
American Radio Relay League
American Television & Radio Co.
Amperex Electronic Corp.
Ashe Radio Co.
Barker and Williamson, Inc.
Belden Manufacturing
Bliley Electric Co.
Bud Radio, Inc.
Burstein-Applebee Co.
Cameradio Co., Inc.
Candler System Co.
Cannon Electric Co.
Centralab
Collins Radio Co.
Concord Radio
Cornell-Dubilier Electric Corp.
Dale Electronics Distributors
Eitel-McCullough, Inc.
Eldico of New York, Inc.
Electric Soldering Iron Co., Inc.
Electronic Instrument Co., Inc.
Electrons, Inc.
Electro-Voice, Inc.
Erie Resistor Corp.
Federated Purchaser, Inc.
Fort Orange Radio Distributing Co.
Freed Transformer Co.
Gates Radio Co.
General Electric Co.
Hallicrafters Co., The

Hammarlund Mfg. Co., The
Harrison Radio Corp.
Harvey Radio Co.
Harvey-Wells Electronics, Inc.
Heath Co., The
Henry Radio Stores
Hudson Radio & Television Corp.
Hughes Research & Development Labs
Illinois Condenser Co.
Instructograph Co.
Insuline Corporation of America
International Rectifier Corp.
International Resistence Co.
Johnson Co, E.F.
Kenyon Transformer Co., Inc.
Kieruff Electronics, Inc.
Knights Company, The James
LaPointe-Plascomold corp.
Macmillan Co., The
Mallory & Co., Inc., P.R.
Master Mobile Mounts, Inc.
McElroy Manufacturing Co.
Measurments Corp.
Merit Transformer Corp.
Midland Manufacturing Co., Inc.
Millen Manufacturing Co, Inc., The James
National Co., Inc.
Newark Electric Co.
Ohmite Manufacturing Co.
Par -Metal Products Corp.
Precise Measurments Co.
Precision Apparatus Co. Inc.
Radio Corporation of America
Radio Products Sales, Inc.
Radio Shack Corp.
Shure Brothers, Inc.
Shurite Meters
Sprague Products Co.
Standard Transformer Corp.
Superior Instruments Co.
Supreme, Inc.
Terminal Radio Corp.

>Clear as mud describes it very well.
>

You can make case with the NEC all day and it almost always comes down to this in real practice:

1. If you are using a licensed electrical contractor, what is their master electrician's interpretation of what's required?... by the way, much of her/his interpretation will be based on (2):

2. How does the local code inspector interpret the installation, and the NEC? This varies very widely from locality to locality, and even inspector to inspector, in a large metropolitan area. Whether the interpretation is right or wrong, she/he's the one who has to sign it off. Once signed, it's "code". Fighting their interpretation (right or wrong) usually only alienates them, unless you're a really politik. If you can find out who your inspector is, and they are willing to answer a query before the job is done (not always the case), then you will know which way to go. Often you just have to do it the best you can, and be prepared to rework when the inspection takes place. This is a fact of life in the electrical construction industry, and one that often causes much consternation for contractors (especially when just starting their business).

73 and good luck,
monty N5FC

Don't *ever* use it on clear plastics, front-panels, etc.

Also, try spray-on 'electronics wash'.

'Nifty' spray from supermarkets works great, especially
removing smoke/tar/grease, etc.

The best thing I've found for cleaning old equipment is auto bug and tar remover. I've used it lots of times for removing labels and glue residue from front panels. Its strong enough to soften the glue and remove dirt and even some pen marks. I've never had any problem with it damaging any paint or plastics.

Not sure about using it around switch or socket contacts though. I think I'd go with the alcohol for that.

Very true what you say!! I agree...My local inspector interperts a separate building as any building that is not connected to the main building in any way, if there was a connection such as a roof line or breezeway its considered the same building and therefore any electrical panel in the out building would be considered a "sub panel" and therefore the codes concerning "sub panels" would apply. So if the building is not connected in any way then the panel in the "separate" building would be wired like a "main panel" of the main building, however, the separate building panel may be fed by the main panel from the main house. The main difference between a sub panel and a main panel is the nuetral/ground configuration. On a sub panel all nuetrals and grounds must be separate and no separate ground rod. In the case of a panel in a separate building, the nuetral and ground WILL come together and a separate ground rod for that building is required. So it would be treated as a separate service (so to speak) even though it is fed from the main building.
I have found that on most occassions if you ask the local building inspector what HE wants to see when he inspects the job, he will TELL you. It will save you alot of grief afterwards. You may be right and he may be wrong, but the only way to solve the problem would be to appeal to the STATE electrical inspector for a mediation, that could take time,so better off to make a call to your local inspector and discuss the job before hand. In most cases they will answer your question AND alot of times, in GREAT detail, especailly if its the first time you are working in his juristiction......Cheers......Louie

I envy your attitude!
I'm a consummate builder at home and at work.

If I could only FIND folks, blind or otherwise, that had that thirst for
building.

I hold Ham Radio night every monday night at my house to help folks learn
and build "Stuff" and the numbers of interested folks are dropping off.

Increased ripple current, DECREASED Ripple voltage, perhaps increased average voltage.

> 2: What Do You Suggest. ?

GO for it! (Maybe add current limit resistance?)

> 3: Would Quality Of The Output Be Degraded ?

I doubt it. The times I've done it, the output was MORE stable.

I vote soapy water & toothbrush, then clear water rinse, but be
sure to dry it thoroughly before powering up.

Isopropyl probably wouldn't do any harm, and would probably
dry faster.

Good luck!
Rich

if they're the same voltage they'll improve regulation...
one thing i'm not sure of is whether or not the recitifer pack can
withstanding the greater surge when you first turn it on..
if it can't it'll short and you can always replace it with newer higher rated
diodes..
or do it at the same time..
you could install a small resistor preferably a globar if they still make
them..
good luck
hank

Would tend to decrease power supply ripple, and slightly increase B+.
However, the increased charging current may be hard on the rectifiers unless
you use a step-start or other inrush current limiting scheme.

There's one more reason, of course: the high power causes something in the load to change. The load could be simply non-linear, or it could suffer from heating effects.

Ralph,
It sounds like you are a very considerate operator. Many times,
I've encountered the signal of someone 'tuning up' on the air with a
heckova lot of power. Out of disgust and curiosity as to who and why,
I'd listen to the entire tune up procedure, just to see who the yokel
was, when he started his "CQ". Maybe it is a coincidence, but in every
instance this happened, the operator began speaking in a Spanish
dialect. Maybe this is the approved method in South American countries.

Hi,
It is getting very difficult to find new 500V caps. Therefore the only solution is to use 450V caps which is being used for Power factor correction switching power supplies. Since you use 8 of them, it will make the total voltage to 3600V which is more than enough to handle 572B's because the maximum voltage to this tube is 2500V. You can actually improve the power supply high voltage regulation by using larger capacitance caps like 220 uF. New technology enables the size get smaller so you can find the same size as the original ones with twice the capacitance. You can try electronics distributors like Future electronics for Rubycon, United chemicon,Elna,Nichicon who makes excellent quality parts.

Good luck.

Or arcing. This happens easily if you try to run high power through a tuner to a load that has high SWR. The voltages can become quite high. I have arced across the phenolic insulator of a PL-259 by doing this. A carbon trail forms and it will arc more easily after the first time. If you need to run more than 100W into high SWR, consider teflon-insulated connectors, and check the working voltage of your feedline. Some, such as RG-8X foam, won't tolerate much SWR at 1500W.

Cheers
Carl WS7L

If the finish is lacquer, try either Acetone or Lacquer Thinner.
If it's an oil-based enamel, try chemical paint stripper. Both
should be available at hardware stores. Ladies' finger nail polish
remover often contains Acetone.

I seem to remember using a match or cigarette lighter to burn the insulation off. Of course, it stinks (and the by-products probably aren't healthy to breathe).

Dave

What a great idea! Now if only I could get folks interested in
building "stuff" around here!

I have enjoyed 19 years of building so far, and look forward to many
more. To me it's (in most cases) more fun than getting on the air to
use the stuff I've built. For every rule there is an exception, and I
will admit I'd rather be digging weak ones out of the noise on EME
than sitting at the workbench with a hot soldering iron...

you might need to put in a wire wound surge resistor to protect the rectifiers.

And a fuse to protect the tubes / amp deck if there is short.

NO MATTER WHAT Make absolutely sure the bleeder resistor is good! Else you could become a silent key. You would have 4.5x the prior capacitance. 48 mfd @ 4kv will take a finger right off!

It is a good idea to use the same voltage .... if they will fit.

Let's see: at SWR = 1:1, Power = CurrentSquared times Resistance, so
Current = SQR(power/Resistance) = SQR(350/50) = 2.6+ amps.

Add some more for the SWR.... ???

3015. Determining Trap Resonance with MFJ 259B

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-11 00:00:00 UTC
From: Gary Ferdinand <gferdinand@ipass.net>
Message-ID: <rgRI4.177$xO4.790@saturn.ipass.net>
Source record: 61620

Anyone have experience using an MFJ 259B analyzer to determine the resonant frequency of a coaxial trap? Specifically, I'm looking for guidance on the following:

1. How to set up a test bench. How to couple the MFJ to the trap? Any precautions in the environment to avoid skewing the measurement? Here I'm talking about getting the trap at the proper resonant frequency PRIOR to hooking it into the antenna.

2. Verification of how to correctly read the result. I'm presuming I set it up to read impedance and then tune the frequency to PEAK the impedance (the trap is a parallel LC and should look "infinite" at resonance)?

3. With respect to antenna (dipole) construction, I am planning to feed the highest frequency band with the first pair of traps first, and cut the inner wire for best match at chosen frequency. Then add wire and the next trap and do it for the next lower frequency band, etc., down the bands. The plan is for a brute force (3 traps per side) 10/12/17/30 meter dipole. Anyone have a better method or see any pitfalls in this one? (Other than the usual remarks to "have fun" cutting and twisting!) For a while I thought of trying to lower the number of traps by tuning a pair between two bands and making use of the capacitive or inductive reactance to lengthen/shorten a 3/2-wave affair (30-to-10), but decided I wasn't smart enough for that and am going the brute force approach.

4. Any gotchas from the school of hard knocks?

TIA/73,

Gary W2CS
Apex, NC

The most reliable way is with a heat stripper. Unfortunately, the fumes from teflon are extremely toxic and you must find a way to avoid breathing even the least bit of it. I did that once and thought I was going to die.

I red hot wire will melt the teflon away from the conductor.

MFJ sells a grid dip meter accessory for the impedance meter but you can make one with just a coil. Put the coil across the terminals and use it to couple to the inductor of the trap. Tune the meter until you hit resonance; it will be obvious. If the Q is reasoable, the peak should be sharp.

You might want to try building an antenna without traps. Make a series of dipoles for each band and connect them together at the center, use a balun and run one feeder.

Or you can try what I did. I built a 2 element yagi for 12 and 17 meters. I feed the 17 meter driven element with a balun and coaxial cable. The 12 meter driven element is coupled just by being a few inches away from the 17 meter driven element. It works great.

I use a grid dip meter - an ancient Heath GD-1B. Does the 259 have an accessory
coil that turns it into a dipper? That's how I'd test them.

>Specifically, I'm looking for guidance on the
>following:
>
>1. How to set up a test bench. How to couple the MFJ to the trap?

Inductively. Connecting wires to the trap, even short ones, skews the
measurement.

>Any
>precautions in the environment to avoid skewing the measurement?

Trap should be a foot or more away from anything metal. Coupling should be very
loose. Hanging a trap from the ceiling on twine or monofilament is not a bad
idea at all.

> Here I'm
>talking about getting the trap at the proper resonant frequency PRIOR to
>hooking it into the antenna.

That's exactly the right way to do it. And once you have them set up, don't
fool with them.

I use the trap construction described in N4UU's article in December, 1984 QST.
I have found that coax and PVC pipe manufacturing tolerances are such that you
need to make a test trap to get the right size. I have done several posts on
this in rraa - you can see them in deja.com.
>
>2. Verification of how to correctly read the result. I'm presuming I set

Yep. When using a dipper, you want the dip frequency.

>enough for that and am going the brute force approach.

I would just build the whole antenna, and see where the minimum SWR points are. Then I'd adjust the innermost wires to get resonance on the highest band, then the next-outer wires to get resonance on the next-lower band, etc. There is always some interaction. Don't do your adjustment at the trap connection itself - put pieces of wire on each trap, and have a splice in each wire section for adjustment.

To make adjustment easier, get a handful of "split bolt" connectors from Home Depot or an electric supply house. Also called "bugs" or "Burndys", these look like a bolt and nut combo in which a slot has been cut longise in the bolt. You just lay two wires parallel in the slot and tighten the nut to make a tight electrical and mechanical connection. Use them to find the right lengths, THEN make good solder joints and recover the "Brundys" for the next project. They're not cheap, but they sure make the job easier.
>
>4. Any gotchas from the school of hard knocks?
>
YES!!!!

Coaxial-cable-and-PVC-pipe traps are NOT perfectly symmetrical. That is, it matters which end of the trap goes towards the feed point! I had all sorts of confusing results when trying to duplicate an antenna because I was putting the traps in differently after each adjustment!

Either way will work, but you get different wire lengths one way vs. the other. (I'm talking about traps where you wind a length of coax on a piece of PVC pipe, then connect the inner conductor of one end to the outer conductor of the other. The "free" ends are connected to the antenna. N4UU style). I settled on the convention of "the center conductor connection goes towards the center of the antenna" but it doesn't matter (in my experience) as long as you do it the same way on both sides of the dipole.

W8NX has done some really good articles in QST, too. But my "bible" is the N4UU article.

Refer to the huge, noisy, and flamer-filled thread called
"energy sucking antennas." Briefly, the idea is that
a very small radio antenna can intercept approximately
the same amount of energy as a dipole antenna which is
1/pi wavelengths long. To create this effect, make the
small antenna be part of a resonant circuit. For example,
to make a small loop antenna act "large", put a variable
capacitor across it, then tune it to resonate at the frequency
that you're trying to receive. Or, to make a tiny dipole
"suck in" more EM energy, put a variable inductor across
it and tune it to resonance. If the Q of the resonator is
high, the effect is much larger.

The other half: a couple of physics papers suggest that
this explains why atoms can strongly interact with light,
even though atoms are typically thousands of times
too small to act like good antennas. A 0.1nM atom can
emit and absorb 600nM light. If we imagine it to be
a high-Q resonant circuit, then its strong interaction
with a particular frequency of light is sensible.

For a hyper-simplified example of how "small resonant
antennas" behave, see:

http://www.amasci.com/tesla/nearfld1.html

Here's another version aimed at fringe (crackpot) experimenters.

Bzzzzzzzt. Your description here indicates that you still will attempt deception to obtain agreement to something not stated based on something that in general says nothing, but isn't objectionable apart from the rest of the conditions that are conveniently missing. The part you left out is where any disagreement begins. It's completely obvious that one can paramaterize any criteria regardless of what the physical implications are so long as one doesn't try to claim that it bears any resemblance to the physics. Your antenna requires the following additional constraint: 100% of the radiation through the cross-sectional area of the unoptimized antenna has been accounted for and that making the system resonant pulls in more than that by depleting the region surounding the antenna of radiation, which violates quite a list of physics that I and most people would regard as rather serious shortcomings for anything without ironclad evidence. With a lot of effort and a clothes pin on my nose, I can keep it from violating conservation of energy, but not without even more distasteful problems as a result.

You also have not explained why your model is justified in regarding the plate separations of your capacitors as significant enough to affect the resonance point, but at the same time be so far away as to be negligible for any other reason, like, the E-fields. I, mean, I think I know the reason, but I was more interested in one connected to the physics.

If my monitor shows 1.5 screenfulls of text, does it get bigger just because I display it? Or is it because I shrunk the fontsize and redefined a screenfull to be a standard value for which mine is 1.5 times the size? Same thing.

I think he's saying that this is a surprising result which very few people are aware of. I personally noticed this phenomenon ten years ago when I was a grad student in Electrical Engineering, and surveyed half a dozen professors of antenna theory in my university. None of them knew this fact, and in fact most of them insisted that it couldn't possibly be true. For a while, I made a point of talking to professors at other universities about this phenomenon whenever I happened to be travelling, and I found more or less the same level of awareness whenever I went. Out of ten professors of electromagnetic theory, I didn't find a single one who agreed with Bill's statement as quoted above.

By the way, from Bilge's postings, I can't figure out whether he agrees or disagrees with Science Hobbyist's basic claim.

That's amazing, since it's clearly explained in even the first edition of Kraus' _Antennas_, by far the most widely read basic antenna text. And it was published in 1950. In their classic work on antenna ground systems, "Ground Systems as a Factor in Antenna Efficiency" (IRE, 1937), Brown, Lewis, and Epstein do a simple derivation and conclude "Thus an antenna of infinitesimal length, subject to no losses, yields a field strength which is only 4.25 per cent less than the field from a quater-wave antenna." Surely this derivation has been prominent in just about every text published for the last century or so.

I thought it was just me who had professors who had their heads where the sun don't shine. (Although I have to say, my electromagnetics professors, Carl T.A. Johnk and Leonard Lewin, were among the absolute best.)

It was, but quite a few people DIDN'T know it before this thread
started. It's the same as Transient Intermodulation Distortion (TID) in
audio amplifiers. Matti Otala was flamed something rotten for 're-
discovering' it by the people who already knew about it. BUT, many
amplifier designers DIDN'T know about: that's why Otala was able to show
that some quite well-known amplifiers suffered from it. I only found out
about it one year before Otala first published in English. But it's
obvious once you 'see' it.

I'm looking for help steering me to an article I saw
for a solid state synchroscope as used for synchronizing
two alternators - only instead of the usual two lite
bulbs, this one utilized a crystal oscillator comparing
60 Hz emergency alternator power and displaying it on
LEDs arranged in a circle that rotated with phase dif-
ference.

I could design my own but why do that when I can use
ideas from another working unit?

I've searched the yearly index for Ham Radio and Com-
munications Quarterly in addition to keyword search
on the ARRL member site. Not recalling the name of
the article complicates things considerably.

Anyone come across it and remember where I saw it?

I haven't heard that name in a long time. I own one of the
original electrocompaniet 20 Watt amps. I'm lucky if people
that sell stereo equipment know what it is, much less who
designed it. Not only is it nice amp, it doesnt catch fire
driving quads.

Not unless there is anything controversial about the way any
antenna works. Radiation lands on them, providing the right
boundary conditions lets the energy roll out of the antenna
go to work.

> about every text published for the last century or so.

And yet a good number of the responses here and on the
other newsgroups were along the lines of "let's disprove
this obvious crackpotism."

One aspect of the phenomenon is that, in the case of a
transmitter, it's obvious that we can easily adjust the
volts/current of the drive signal to crank up the strength
of the tiny antenna's fields, and make the antenna act
"large." Give a loop antenna a large current, or give
a short dipole a large voltage. If the field strength
at 1/2-wavelength distance is just as strong as that of
a larger antenna, it makes sense that a small lossless
antenna would transmit just as well as a large one. But
when the same is done with a receiving antenn, so that
the tiny antenna generates enormous local fields and
"sucks energy" from surrounding space, many people refuse
to believe it.

As others pointed out to me, reciprocity considerations
should convince us that this can occur for reception just
as it occurs for transmission. Even so, the very nature
of the "energy sucking" effect seem to anger some people.
I don't really understand why.

==========
Roy, you've been extolling the virtues of B,L & E to me for ages.
Unjustly accusing me of differing with their (unspecified)
conclusions.

If that's the best conclusion they could come to after all their
theoretical and practical research, then I wonder who paid their wages
and who they were plagiarising ? It doesn't give me much confidence
in their other conclusions - whatever they were.

It was quite obvious to workers 30 or more years before BLE, a
loss-less antenna lays down a field strength, referred to a standard,
which depends entirely on its radiation pattern in the horizontal and
vertical planes. The 4.25 percent is merely the difference along the
horizontal between a 1/4-wave vertical and a very short vertical
antenna. (Incidentally, the gain along the horizontal is a maximum
with a 5/8-wave antenna. MF broadcasters depend on such facts.)

Unfortunately Eznec cannot be used to check this point because she
always reports radiation along the horizontal to be zero - regardless
of the antenna configuration or ground conditions.

Source record: 61464

"Ed W." wrote:

> Is there a reliable way to strip #30, double E, and single E, stranded
> teflon wire without nicking and breaking any of the
> conductors?.....

Hello--

Believe it or not, you can use a manual wire stripper. There are two styles--
one made by J. W. Miller and countless offshore imitators that looks like two
flat blades with mating notches in the jaws. The secret is to grasp the wire
in the jaws and apply just enough force to "crunch" the insulation. Then, you can
pull off the insulation with your fingernails.The process is hard to describe, and it
takes a little practice to get the "feel" of the tool you're using.

Some of the imported tools are junk-- avoid any with lateral wobble in the jaws.

Also, General Cement (GC) manufactured a more-complicated stripper that
uses flat, notched jaws to grab the wire and sever the insulation. The notches
are calibrated by wire gauge, and you need two tools to handle the range
AWG#14 to AWG #28. I don't know whether this tool is still made, or what it

was called.

Finally, there are thermal-stripping tools that look a little like giant tweezers
with small electrodes running across the jaws' faces. You press a foot pedal,
the electrodes heat red hot, and you grab the Teflon wire and twist--
again, this
is easier done than described. Not too much Teflon gets vaporized, but good

ventilation is recommended.

After using various kinds of wire, I prefer Teflon insulation, with irradiated PVC
(105C-rated; also called IPVC) a distant second. Regular PVC turns to mush
and smells almost as bad as overheated Teflon.

John Fields said some stuff about
>
>What idea?
>

Briefly, and without rhetoric, the claim was that adding passive components to a small antenna so that it resonates at the frequency of interest will cause it "pull in" radiation that otherwise would not fall on the antenna. This must be distictly contrasted from the case that the radiation strikes the antenna regardless and that any added components can only optimize the power transferred from the antenna through the commonly available tools of halliday & resnick level physics. It's not that only three people grasp the idea. It's that of those that do, only three have considered supporting some aspect of it. I don't happen to be among them. The confusion is in part due to the legitimate point of view that one may take by defining everything in terms of a standard efficiency, size and directionality (e.g., isotropic) and quoting an equivalent antenna geometry in terms of a standard. The "energy sucking" amounts to choosing the normalization to unity backwards and attributing the additional signal to a real effect.

You can easily build your own dip adapter for the MFJ analyzer: it consists of just 2 resistors, 1 capacitor, and a 3 turn coil. Complete construction and usage instructions appeared in the Nov 93 QST, pp 45-46. Email me if you can't easily locate a copy.

Construction details of my attic-mounted 6-band trap dipole are at:

>
>
> Not unless there is anything controversial about the way any
> antenna works. Radiation lands on them, providing the right
> boundary conditions lets the energy roll out of the antenna
> go to work.
>

I don't think this is a good way to think about antennas. He makes
it sound like the energy available to do work depends on the
physical cross-sectional area of the antenna. I wonder if this
is what he believes? The point raised by Science Hobbyist is,
of course, that antennas don't behave this way.

Assuming you only want to clean the end for connection...

Some enameled (painted) wire uses material which will
decompose at soldering temperatures, others, not so much.
If you have the type that will decompose, touch your
soldering iron (~700 degrees F) to the exposed end of the
cut wire and apply a little solder/flux. Move the iron down
the wire as it heats (and the insulation decomposes) adding
solder/flux.

3067. FS: Heathkit SB-104A w/PS - needs work

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-14 00:00:00 UTC
From: Christopher An <christopher_an@sympatico.ca>
Message-ID: <38F69F49.F63EA26A@sympatico.ca>
Source record: 61472
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.swap,rec.radio.amateur.equipment

Hi,
I have a Heatkit SB-104A HF transceiver for sale. It needs work!
I tested it with a signal generator and it receives strong signals like S9+++, but the audio is very weak and I can't hardly hear any weaker signals. I tested same thing with on air signal, and I can barely hear S9+++ signals only. The frequency display is totally blank.
Physical shape is very good. The front is excellent and the top and bottom cover has some minor scratches. All knobs are original and in excellent condition. There are some signs of repair (or modification) attempt. No noise blanker or optional filter. It is clean inside, and all works seem to have been done properly. There is a callsign (Canadian callsign) on the display. I checked the meter and it works fine. There is no missing parts, but I took out some ICs from a board and did not put them back.
If anyone looks for a nice project, this can be yours. I don't have any expertise nor time to work on this radio. I got this from local fleamarket as a working condition radio, but it did not work when I turned it at home. I don't remember the seller, so I have to take the loss.
My price is $135 plus $15 for shipping anywhere in Canada or Con. US. The power supply is pretty heavy and the actual shipping must be around $35~45.
The power supply is HP-1144 and powering off from the radio turns off the power supply as well. Power supply is in very good condition, and works great.
I believe my pricing is reasonable, but you can fix it if you think I was wrong. I think the power supply itself has about $60 (or more because it is 20A PS) value and the radio is about $75 as a part radio.
I will ship it by UPS with proper packaging. Payment can be made by personal check, money order, or certified check (cashier's check in US).

Thank you for reading this long for-sale posting and 73,

Christopher VE3UVT

Bob:
Yea, I'll bet? I was told that the gas eminated is "Fluorine", pretty corrosive and toxic stuff?
I have a simple pair of "Miller" sissor-action stripping tool, but somehow keep nicking one or more strands which seems too much to sacrifice? I am having some success by "smashing" the end of the teflon with a pair of "duck-bill" pliers and then carefully cutting "behind" the flattened tip region with a razor blade? After that, I grab the flattened portion of teflon with a pair of serrated, needle nose pliers and pull? It is not foolproof, but seemingly better than the reg. stripper. I probably need a new pair of strippers also? A guy was demonstrating a pair of automatic strippers at the last hamfest, but I didn't have a sample of #30 TFE with me? The next time, I will. TFE has a nice glossy, translucent appearance for my particular application or else I would switch to something other?

David Green said some stuff about

>I don't think this is a good way to think about antennas. He makes
>it sound like the energy available to do work depends on the
>physical cross-sectional area of the antenna. I wonder if this
>is what he believes? The point raised by Science Hobbyist is,
>of course, that antennas don't behave this way.
>

What else would it depend upon? You certainly cant have MORE average
energy available than the flux in the solid angle your antenna subtends,
and it isn't any less silly to think there is less flux than there would
be through the same area if the antenna wasn't there. You certainly
cant expect the radiation to notice the antenna way off in the distance
and tell the source to alter the angular distribution of the radiation.
(we ARE dealing with radiation fields here - so the antenna isn't coupled
to the source through capacitance or a wire -- the usual conditions).
The next step would be to add in the fact that you have to deal with a
probability distribution rather than simple rays, but that also lends
itself to a symmetry argument when considering the time averaged flux.

What exactly happened to invalidate conservation of energy or
gauss' law? If I draw a sphere centered on the source, up until
some any radiation is absorbed, how can the angluar distribution
of the radiated flux change just by going to larger r?

Regardless of whether this is a good way to view an antenna for most
of the characteristics one might want to know, if one may apply this
point of view to avoid calculating something, the the wrong way to
look at the problem is the way that requires a calculation. I would
find it rather bizarre if someone were to argue that the answer calculated
from a number of numerical approximations and idealized behavior was better
than simply recognizing the calculation would be pointless. I didn't
simply memorize a collection of facts as I strolled through the physics
material. Why should I waste a perfectly good method of solving a
problem just because other people choose to do it the hard way? In
the case of the "energy sucking", I think it not only reduced the problem
to one of simple geometry, the fact that the geometric dependence
is a nice physical reason, that it beats the hell out of the claims
for the existence of "ebergy sucking" based upon some uninvestigated
speculation about the "near-field" of the antenna "reaching out" for
additional radiation and physical violations that needed to support it.

I didn't see anyone argue that the presence of an antenna
invalidates the 1/r^2 falloff of the radiated power, so I cant

see why there would be an issue.

That's odd. I thought the "energu sucking" was the target of all
the remarks concerning "obvious crackpotis". I dont see any
similarities that would allow you skate in behind anything
legitimate. It would appear that in the first case, the authors
took limitating cases of the mathematics to show that so long
as the criteria were met, this is what is expected. That is quite
a bit different from invennting a phenomenon for which the sole
evidence of its existence hsppens to be your claim that it does
snd connecting the unsubstantiated evidence to the invented
phennomenon through a theory that has no precise meaning beyond
handwaving arguments that violate conventional physics, while
adding nothing. Doesn't it seem odd that there was no inconsistency
until you "fixed" a problem that wasn't "broken"?

Your theory isn't even up to the level of a consistent hunch in
search of a problem to speculate about.

> transmitter, it's obvious that we can easily adjust the
> volts/current of the drive signal to crank up the strength
> of the tiny antenna's fields, and make the antenna act

If it's so obvious, that this makes sense, much less is
true, then illuminate me. If this is a receiving antenna,
I fail to see what you are cranking up and if it's a
transmitting antenna, your conclusion about "large"
doesn't follow from the obvious increase in power output.

Since when does physical size have any fundamental relationship
to the total radiated power? Power is measured in J/s
sizes are in meters. The only connection occurs when one

defins something like an X-watt antenna to be a legnth
of 1 meter. Then by your definition, a 2X watt antenna is
bigger.

I'm sorry, but your implicit definitions of personilzed standard
units of measure have not been elevated to the status of a physical
phenomenon.

> "large." Give a loop antenna a large current, or give
> a short dipole a large voltage. If the field strength
> at 1/2-wavelength distance is just as strong as that of

What happened to the numerical results from even the simple
model that was supposed to make some part of this plausible?

> a larger antenna, it makes sense that a small lossless
> antenna would transmit just as well as a large one. But
> when the same is done with a receiving antenn, so that
> the tiny antenna generates enormous local fields and

There is no way any of this makes sense via a logical
progression through the premises. If you get the right
answer (.e.g., increase rather than decrease) it's by
the sheer luck of having a 50-50 chance. Try the results
of a random walk instead of what you seem to think is a
logical conclusion that lead you the "energy sucking".
So long as the random number generator wasn't constructed
with equally fallacious assumptions, it'll get the right
answer 50% of the tim, too.

> "sucks energy" from surrounding space, many people refuse
> to believe it.

Well, failing to adresss one or two bazillion inconsistencies
over the last two months or so is beginning to strain your
credibility. Now, it might be difficult to understand why
"Because, it does", just doesnt elimiate any room for doubt,
but some people just think no evidence + no need + the
working theory it blows out of the water adds up to prefering
something more substantial than your proclimation on a stone
tablet.

> As others pointed out to me, reciprocity considerations
> should convince us that this can occur for reception just
> as it occurs for transmission. Even so, the very nature
> of the "energy sucking" effect seem to anger some people.
> I don't really understand why.

Because your idea of reciprocity involves first finding the
recipricol and then inverting the noralization. This is just
a guess, but probably a safe one, that in normalizing to
a standard value, such that e.g., one replaces a radiation
pattern that is isotropic, that they don't also refer to

the isotropic value as equal to the lowest value in the
in the original non-isotropic pattern by invoking conservation
of energy and the calling the large lobe an enhancement from
something inexplicable.

You deliberately start from a poor efficiency and call it unity.
How is recirpocity involved if you never consider the fact
that you scaled the energy to start with and called the outcome
absolute without ever inverting the scale?

Early on, this like any other question was perfectlly understandable
as a misconception, even through attempts to prove the misconception
wasn't yours. After failing to address any inconsistency between
your idea and reality with anything you forestalled an immediate
end to this crackpot scheme with a superfluous "flame" tangent.
I mean really. When referring to someone that has done the
the equivalent of holding their breath until they turn blue as
a means of repeating the "energy sulking" mantra and avoiding
it's lack of soundness, you have to really be out to lunch if
you think, of all places, usenet is an improper place to not be
polittically correct or provide the appropriate abuse. Call it
flaming, whatever. Save "high road" moralistic musings for for a
wine and cheese party. Either put up, shut up or live with you
choice to do neither. If you want politically correct abuse,
see if there's an alt.miss.manners.

This is true of horn type antennas, but wire antennas generally capture more energy than is incident on their physical structures. For example, Balanis shows in his "Antenna Theory Analysis and Design" (p.84) that the maximum effective area of a short dipole is 0.119 x lambda^2. He goes on to show that for a dipole whose length is lambda/50 that the maximum theoretical effective area turns out to be 5.95 x lambda, over 1700 times the actual area of the antenna.

I would hesitate to call this "energy sucking" but it does show the effect an antenna has on the surrounding space. Of course, a spherical array of dipoles covering the entire area of 4pi x r^2 will interact with each other such that no more energy is received than is transmitted, but an isolated antenna appears to get more than its "fair share".

Paul OM,

I heartily agree, except I also enjoy operating with my own gear just as much as building it!
It has been my observation over my 45 years of hamming that folks are either interested in and have the internal motivation for building and tinkering, or they do not. If not, no amount of hand-holding, cajoling, or whatever will get them interested/motivated. I think we are living today in a Golden Age for ham radio homebrewing. Never has it been easier, or cheaper, to build great gear. There is a lot of homebrewing going on, and not just by the QRP boys. Now, hardly any mechanical work is required either. I've been having a ball the last few years. Yet now, (as before, at least postwar) builders are in the minority of hams. So it is not the opportunity that is lacking in most cases. It is lack of technical interest, that's all. If you're really interested, you will find the information and resources to pursue it. As the old saying goes, "..you can lead a horse to water, but you can't make him drink".
This is a great time to be a ham if you enjoy building.

Happy homebrewing!

Joseph Legris said some stuff about

>This is true of horn type antennas, but wire antennas
>generally capture more energy than is incident on their
>physical structures. For example, Balanis shows in his
>"Antenna Theory Analysis and Design" (p.84) that the maximum
>effective area of a short dipole is 0.119 x lambda^2. He
>goes on to show that for a dipole whose length is lambda/50
>that the maximum theoretical effective area turns out to be
>5.95 x lambda, over 1700 times the actual area of the
>antenna.
>

I'm having a bit of difficulty drawing the same conclusion from
just that information, since I don't see how the effective area,
the real area and an absolute power would be related without
presuming a few things. For example, one immediate change
(I would say reduction, but that isnt clear eaither) is that
this probably has the directivity factored in. That would
produce a 1.5x to 2x reduction, since the best I have been
able to deteermine is that the directivey enhacement is
basically from takining the point in the radiation pattern
that's the largest and then basing the enhancement on taking
that to represent an isotropic source rather than taking the
average radiated power. So, before I can say much, I need to
find the derivation to see what was the normalization.

Since a short dipole is also fatter, in general, do they
consider that in the above or is the factor of 50 in length
the only consideration? That would be misleading if a
50m, 20awg wire was quoted as having a 50 fold difference
in effective area from a 1m x 2cm piece of tubing.

Once I locate the entire derivation, I'll be better able to
comment.

[snip]

Those figures were just a specific theoretical example given
by Balanis. The point is, as he states:

"Thus the wire antenna can capture much more power than is
intercepted by its physical size! This should not come as a
surprise. If the wire antenna would only capture the power
incident on its physical size, it would be almost useless."

I am looking for some resistors that will handle 40 amps at .405 ohms. Does anyone know where I could even begin looking for such a thing? I'm trying to duplicate a battery discharger that will discharge a 28vdc battery at a certain rate.

Thanks

Todd:

I had to do something similar once, and needed a DC dummy load (but for a 13.8 volt system). I ended up using a parallel string of discontinued automotive headlamps that I bought cheap from a local auto parts store (they were happy to get rid of them; I was happy to get them). By wiring both the standard and high beam filaments, I had a pretty effective dummy load for high currents. You'd need to put them in series/parallel for 28 volts. This is NOT a constant current load, just a BIG resistor. If you need it to sink constant current, you could put some current limiting transistors in the path.

Do you need it all in one resistor ?
are you working with a large budget ?
Do you need a < 1% tolerance ?

If the answers are yes,yes,yes there are sources for this sort of thing, but prices will be in the >$4/watt region. There are a number of people who make >50 watt precision resistors Try http://www.vishay.com/docs/sp_pur_housd.pdf for a start. But they are going to be expensive !!!

If you are on a budget then probably the cheapest way to go would be an appropriate length of number 4 copper wire from Home Depot. The resistance of the wire will change as it heats up. It would be cheaper to monitor current through and voltage across the load than to buy a precision load.

By "physical cross-sectional area of the antenna" I believe
that Green meant, at least in the case of a dipole, the
diameter of the wire multiplied by its total actual length.
Is that what you understood?

Todd:

Your talking about over 600 watts. One possible way to do this is to use nichrome wire heating elements, like the ones used in electric heaters and clothes driers. The ones in clothes driers are rated at several thousand watts...you could cut the sections appart and parallel them to give the resistance you need. Use brass screws and washers/nuts to bolt them to ceramic insulators with crimped wire terminals (don't even think about soldering to them).

They are not too expensive and I have seen lots of them at surplus yards.

Source record: 61400

A friend told me that his 6HF5's (Galaxy V mk2) lasted 18 years and were only down to 80% power. Suppose 6JB6 and 6JS6 last just as long provided you don't sit on the key when tuning.

wonder how long 6146B's will last in a transceiver for an active amateur, working at least a few QSO's every week and several contests on ssb or cw during the year? Mine has lasted 10 years, but I am not so active. Japanese transceivers includes a switch to disconnect heater voltage when one do not intend to transmit

Once suggested - as a joke - to QST Hints & Kinks, that great improvement could be achieved by installing a termometer in the PA compartment. I made several statements as to economical improvements and cost reductions (seems to be very important arguments in America) - just to underline the joke, but ARRL staff didn't understand that it was a joke, hi (maybe a great idea to do, but rather impractical to do)

By physical cross section, I mean the actual area as seen by the source and calculated by integrating the radial vector from the source over the area. Since it's easier to presume we're far away enough to consider the entire area facing the source perpendicular and constant r, just assume it's the area/(4*pi*r^2) or for the cylinder, lD/(4*pi*r^2). I'm not sure what he meant, but that's what I meant.

To the best I can tell, the dimensions in the geometry that ever get quoted as being related to function are the ones that have intuitive appeal in terms of wavelength and so are along the current. A short dipole is considered physically smaller than an ideal dipole no matter how wide it is, for some reason. As soon as you improve it by making it the appropriate width, it gets called electrically large, but everyone still calls it physically smaller, even if the phyaical area has been made twice the electrical area in the process. This is further confused by calling it "superdirective" and defining the directivity as an increase in the main lobe rather than a decrease of the rest of the pattern. They draw an isotropic antenna through the average, but make it sound like this amounts to an increase of 1.5 when they should call that 1 and go down from there. Quite honestly, I find the termonology a mess. It's ridiculous to have standard terms that requires so long just to make sure everyone is talking about the same thing just because the question is slightly different,

If that does not fix your problem, put the end of the wire on an Aspirin
(Acetyl salicyl acid)
and heat it by putting the tip of your soldering iron on top.
DO NOT BREATHE!!! The fumes are VERY agressive.
Works even for multi- stranded magnet wire (Litze).

Other recipe:
Lite a small quantity (egg cup) of alcohol (metanol)
Slowly dip the wire through the flame into the alcohol. This way it won't
oxidize.
Extinguish the flame with a metal cap.
Now you can take the wire out, and solder it.

I'm still not clear if you are talking about the actual cross-sectional area of the physical elements of the dipole, or some form of "equivalent" area which is a function of the electrical characteristics as well. We shall assume that we are only discussing the reception of plane parallel radiation striking the antenna broadside and polarized linearly in the same orientation as the antenna so as to achieve maximum signal strength.

I am quite sure that Green meant the former area - the product of the diameter of the wire used to construct the dipole and its actual length, as measured with a ruler. Let's call it A.

So here is my position (and Balanis's and, as far as I can tell, the authors of your reference):

The area mentioned by Green above, A, is much smaller than the maximum equivalent area of a small dipole antenna, denoted Aem in both our references, perhaps 100s of times smaller. That is, the amount of power receivable by the dipole and deliverable to a load, from a radiation field of P watts/square meter, is much greater, by 100s or even more, than simply AP. It is, in fact AemP. The amount of power available in practice will be less due to losses and

mismatching, but it is still much greater, in general, than AP.

Horn antennas are another matter. In their case, Aem can never exceed A (the physical cross sectional area of the horn aperture, as measured by a ruler) and, in practice, can never even equal it.

The bottom line, as I see it, is that "energy sucking" is an ugly name for the ability of small antennas to extract power from a radiant field in amounts greater than AP.

I've seen a number of VHF/UHF radios for sale (I recall the IC-2000H was one of them) that incorporates a thermal sensor (believe a thermistor) attached to the PA module to reduce output power when the module is too hot. It's not a silly idea at all for longevity, especially in PAs that have 'compromise' heat-sinks (i.e., enough heat-sink for light-duty use but not enough for heavy-duty use).

With these solid-state modules, the power supply voltage is reduced to a driver stage (which is, by the way, how low/med/high power control is usually accomplished) to reduce the output power.

You'd need a power-controlled stage that remains adequately linear for SSB use.

> opinion based upon the person posting?

Yes, I read it, and I did my best to explain, politely, that the 'energy sucking' concept is not new, and that the behaviour of tuned antennas is perhaps not as widely known as it might be. I also cited informally, a paper in which a closely-allied treatment, aimed at the sort of readership that WB says he is concerned with, was given to ferrite rod antennas, and described the 'Passive Amplifier' tuned magnetic antenna, which I am very willing to demonstrate.

I also refrained from flaming WB for going down some unhelpful by-ways in his search for enlightenment.

Joseph Legris said some stuff about

>I'm still not clear if you are talking about the actual
>cross-sectional area of the physical elements of the dipole,
>or some form of "equivalent" area which is a function of the

That's what I'm referring to. The physical area.

>
>So here is my position (and Balanis's and, as far as I can
>tell, the authors of your reference):
>
>The area mentioned by Green above, A, is much smaller than
>the maximum equivalent area of a small dipole antenna,

My reference states explicitly the maximum equivalent area
is <= physical area. To make Aem independent of the length,
the width is left arbitrary, but always satisfies the
criteria that its physical area id at least as large.

>dipole and deliverable to a load, from a radiation field of
>P watts/square meter, is much greater, by 100s or even more,
>than simply AP. It is, in fact AemP. The amount of power

If that that thells you how wide it is, tell me the dimensions
of a dipole that is designed to receive a wavelength 1/50
of its length compared to an ideal. If your formulae and
derivations state what you imply, they should give all those
dimensions because it certainly isn't true that the diameter
can be arbitrarily chosen.

>The bottom line, as I see it, is that "energy sucking" is an
>ugly name for the ability of small antennas to extract power
>from a radiant field in amounts greater than AP.
>

I think the same mistake in what is normalized is the source
of confusion.

>
I thought we were discussing a small dipole, e.g. 1/50 of
the wavelength, not 50 times the wavelength. Continuing...

In the example I quoted originally from Balanis where the
actual length of the antenna is lambda/50, Aem = 0.119
lambda^2 and the maximum effective electrical width is shown
to be 5.95 lambda. That's where he got the value of of 1785
times the actual physical width of the conductor which he
gives as typically lambda/300.

So to put actual numbers there, let lambda = 1 meter. The
dipole is only 2 cm long. The actual width of the dipole
elements is 3.33mm, but the maximum effective width is 5.95
meters and the Aem is, of course, 0.119 square meters. All
from an antenna of actual cross sectional area of 6.67 x
10^-5 square meters.

>Any advice is welcome! KE4QOP John

I would take a look at the MFJ-971. It's priced only a little higher than a manual 'QRP' tuner, but it has an actual SWR meter instead of an LED and a wattmeter with a 6 watt full scale range. Plus, it will do 300 watts (or so they claim - but I would believe >100) so when you use your QRO rig you don't have to take it out of line.

Hello All

I'm sure I read somewhere that you could make PCB's by an impact ironing-on process involving just a humble smoothing iron and some sort of direct contact with the copper clad board with an acetate sheet.

Have trolled around various sites but no luck. I am familiar with Ferric Chloride etching etc. Not tried the UV method however.

Any ideas, URLS, tips please?

Many thanks... Ken

3106. Guide to the rec.radio Newsgroups

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-15 00:00:00 UTC
From: jeffreyh@Hawaii.Edu
Message-ID: <8d8qm0$61n$1@news.hawaii.edu>
Source record: 61487
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Archive-name: radio/personal-intro

This message describes the rec.radio.amateur.*, rec.radio.cb, rec.radio.info, and rec.radio.swap newsgroups, as well as their Internet mailing list counterparts and complements. It is intended to serve as a guide for the new reader on what to find where. Questions and comments may be directed to Jeffrey Herman, KH6O, jeffreyh@hawaii.edu, or Paul Schleck, K3FU, pschleck@novia.net.

This message was last changed on 14 March, 1998.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions were held on the mailing list, and sent to the mailboxes of those who had signed up for it. When the Usenet software was created, and net news as we now know it was developed, a newsgroup was created for hams: net.ham-radio. The mailing list and the newsgroup were gatewayed together, eventually.

Over the years, as the net grew, the volume of discussion became progressively higher. First one by one, and then as part of two reorganizations, what was once one group became many. In the process, developments elsewhere on the net were reflected in the groups as they were created, most notably the change to place all of the ham radio groups in one hierarchy.

The collection of newsgroups continues to grow as more people join the net, and as more topics of discussion gain volume, I expect to see more groups be created as well. This follows what is happening on the rest of the net.

Nearly all of the radio newsgroups have corresponding mailing lists, the notable exception being rec.radio.swap. There are also a few mailing lists that don't have newsgroups.

The Current Groups
==================

It's important to post messages to the group that's appropriate for them, and not to the groups that aren't. The whole idea of having different newsgroups is so that folks who aren't interested in, say, homebrewing, don't have to wade through messages about homebrewing on the way to read about Field Day. Posting appropriately is just good etiquette.

The rec.radio.amateur.misc group is the catchall. It is what rec.ham-radio was renamed to during the first major reorganization. Any amateur radio-related message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, was removed on September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there. To answer a frequently asked question: No, there is no mailing list that goes along with this group. If you can't read Usenet news directly, you're out of luck.

The group rec.radio.amateur.policy was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate - it's now legal to order a pizza on the autopatch, if you're not in the pizza business - as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The group rec.radio.cb is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the

group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently David Dodell, WB7TPY. The email address for submissions to the group is rec.radio.info-moderator@primenet.com. Inquires and other adminis-trivia should be directed to rec.radio.info-request@primenet.com. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups r.r.amateur.antenna, .boatanchors, .dx, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas, the older tube based amateur, military, and commercial gear, commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter. The .dx group is devoted to long distance amateur communications. Each of these subgroups has its own charter and FAQ; please refer to the archives to find these documents.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

Mailing Lists
==========

In addition to the mailing lists that mirror the Usenet newsgroups, there also are a few that stand alone. These cover specific areas of ham radio, and discussion is focused on just those areas. PLEASE BE SURE TO SAVE THE WELCOME MESSAGE YOU RECEIVE AFTER SUBSCRIBING -- IT WILL CONTAIN IMPORTANT INFO REGARDING UNSUBSCRIBING!

The cq-contest mailing list is for discussions of contesting in ham radio. To join, send an email to cq-contesting-request@contesting.com.

The DX mailing list covers the finer points of DXing. This one is also joined by mailing "subscribe" on a line by itself, this time to dx-request@unbc.edu.

There's also a VHF mailing list, for VHF operators of the weak signal persuasion. You can join this one be sending "subscribe vhf" on a line by itself to vhf-request@w6yx.stanford.edu.

The QRP-L list is devoted to building and operating gear at low-power outputs. To subscribe, send an email to listproc@lehigh.edu and only write: subscribe qrp-l Your Name.

The TopBand e-list is devoted to all areas of operation on 160m. To subscribe, send an email to majordomo@contesting.com and only write: subscribe topband and follow the instructions you'll be sent.
This site, contesting.com, also hosts a couple dozen other ham-related e-lists. Use the above address, and only write: lists to get the entire index.

The Boatanchors e-list is devoted to the older tube-based ham, military, and commercial communications gear. To subscribe, send an email to: listserv@listserv.tempe.gov and only write: subscribe boatanchors

For homebuilding transmitters and receivers using tube technology, there is the Glowbugs e-list; send an email to: majordomo@piobaire.mines.uidaho.edu and only write: subscribe glowbugs <your@address.here>

The VHF DX discussion list can be accessed by sending an email to: majordomo@blacksheep.org and only writing: subscribe VHF-DX-discuss.

We now have a list devoted to amateur radio history. To subscribe, send an email to: ham-radio-history-subscribe@egroups.com - leave the body of the message blank.

Qth.net hosts over 100 ham-related e-lists, including lists devoted to each state, manufacturer, mode, band - too many to state here. Send an email to majordomo@qth.net and only write: lists to get the complete index.

For one of the most complete indexes of email lists, see the excellent web site http://pw2.netcom.com/~ac6v/pageae.html

Please do NOT send subscription requests to the mailing lists themselves; that doesn't work very often, and is very annoying to those on the list. Also, please keep your electronic mail address current with any mailing lists you subscribe to, as dealing with returned email is a nuisance for the person maintaining the mailing list.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's

headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

EM is a weird beast. You can't simply look at one piece of the system, you have to look at the total field. The receiving antenna is not a simple passive device, it radiates too. It's field has to be added to the incident wave before calculating energy flow and that distorts the 1/r^2 falloff of an isolated transmitter.

Take a look at Schantz's em page, it has some interesting animations and interpretations of em energy flow around dipoles. Here's a link:

http://www.schantz.com/schantz.htm

Mike

Joseph Legris said some stuff about

>Those figures were just a specific theoretical example given
>by Balanis. The point is, as he states:
>
>"Thus the wire antenna can capture much more power than is
>intercepted by its physical size! This should not come as a
>surprise. If the wire antenna would only capture the power
>incident on its physical size, it would be almost useless."
>

That's the part I don't believe follows from what you provided. The diameter of the dipole is never included as part of "effective size" If shortening the dipole by a factor of X increases the signal, the effective area is always X times larger regardless of how much it was simultaneously widened. The extra width is regarded a construction detail to obtain the right impedance. Simply because making such an approximation provides tractable mathematics + an empirical construction detail in an advantageous way to provide rules of thumb for engineering reasons doesn't fly here. I'm explicitly stating that detail is exactly the point. I have a statement from "Antenna Theory and Design", stutzman and thiele, pg 77 stating the same thing, most of which is obvious, but is included for context:

"The available power can also be calculated by examining the incident wave. The power density (Poynting vector magnitude) in the incoming wave is:

S = 1/2 |E x H*| = 1/2 |Ei|^2/\eta

The available power is found using the _maximum effective aperature_, A_em, which is _THE COLLECTING AREA OF THE ANTENNA_ (emphasis mine). The receiving antenna collects power from the incident wave in proportion to its maximum effective aperatures:

P_{aem} = S A_em

... calculation omitted which reproduces your result quoted from balanis, which was:

A_em = (3/8pi)\lamba^2 = 0.119\lambda^2

Continuing below, same page:

The maximum effective aperature of an ideal dipole is independent
of its length, \delta z ...

If it's independent of it's length, then you should find any signal
increase that results from it is due to the increased collection
area that was included "only" by making the antenna physically wider
to meet impedance requirements. Meeting this impedance condition
by adding passive components to the matching network will not acheive
the same thing, if for no other reason, ignores why the the matching
makes any difference in the first place. The impeadnce matching
required by an antenna to the environment is required soley to obtain
the additional are. The change in radiation resistance is precisely
due to the force of the additional incoming photons on the greater
number of electrons.

On page 172, same book, there is a table showing parameters for short
dipoles which shows every advantage gained by shortening the dipole
has an increase in width associated with maximizing its efficency.

As should always be the case, it's quite straight forward to relate the
area to the power using either a wave or particle picture, but in this
case, the wave picture is much more difficult to use than the particle
picture unless you quit at the assumptions used above to derive balanis
result. The problem was, either you or balanis didn't state that the
result is derived from assuming exactly what I stated about areas,
so it's non-sensical to contradict it. Either balanis' later remark
is taken out of context, or it was wrong. I doubt the latter since he
should be in a position to know his own assumptions.

mikegi said some stuff about

>
>Take a look at Schantz's em page, it has some interesting animations and
>interpretations of em energy flow around dipoles. Here's a link:

I'm going to have to take exception to several of his interpretations.
What his descriptions basically show is that they make sense until you try
to ask questions requiring quantum mechanics. He did an excellent job showing
the classical limit. Most of the places he mentions as problematic are right
at the limit of the classical equations he used to obtain them. I dont see
why he chose to stay with a classical description.

Consider his description of a source, where he uses the fields as
an energy storage mechanism that supplies energy to the radiation field.
His picture places the origin of the radiation at a causal surface he
derives classically. His causal surface is what you get from applying the
uncertainty principle and while his approach puts the origin of the
radiation at that point, which he acknowledges is not an odds-on
favorite, it's only the classical derivation that is the problem.
The usual radiation process requires a two vertex ineraction to produce
the radiation field. At one vertex there is a virtual photon and the
real one is radiated from the other. The virtual process is exactly
that energy stored in the fields and which ends up in the radiation
field. The point that he picks for his causal surface, is where the
uncertainty principle would set a limit for the appearance of a virtual
photon with the radiated enregy -- A photon of that energy which is
"further away" cannot be reabsorbed and satisfy the uncertainty principle.

This also solves his information discrepancy where he calls "curious"
the result that he need information flow with no net energy transfer
where he describes the fields as the dipole changes. He mentions that
that one should possibly consider the causal surface as a point of
"of equal and opposite" flow rather than one of 0 _net_ energy flow.
The concept of negative energy in this context is itself a problem.
Again, this problem goes away by not requiring you beat the uncertainty
principle. Appealing to the uncertainty principle may sound artificial,
but remember, the quantities he is calculating are themselves non-
physical quantities that never appear in any real measurement. The
uncertainty principle actually allows you to make such non-physical
calculations where thier non-physical effects never shows up in the
result.

What I don't see is why he chose to ignore the quantum aspects
of the process, which it is clearly not possible to do. Given

that his background as listed on his web page lists john wheeler as an advisor, I would assume the description is the way it is for a reason other than possibly being more amenable for use as an engineering model. I've been to wheeler's talks and from that I'm certain that the person that wrote this description did not suffer from any lack of exposure to the finest speculation in quantum weirdness.

3112. Sidetone injection point?

Hi Thanks for reading,

I have a problem with my ft890 (yaesu)
it will only put out about a few milliwatts on cw but
works well in all other modes.
The drive voltage control is ok and there is a small
increase /decrease in signal displayed on a seperate
rx when the pwr control is adjusted.
Also the sidetone sounds stable,i have not been able to obtain a workshop
manual for this radio so have little info on it.
When i put the scope on the i.f amp
ther is no sidetone detectable when the rig is keyed down?According to the
block diagram i have the sidetoneis injected halfway down the the rf chain
and fed into a pair of mixers,but still no sidetone at this point.can anyone
tell me where the sidetone is usualy injected or any other info would be
appreciated.

TIA Dave mw5adj

I'd recommend you build a solid state discharger.
Power transistors or FETs can maintain the current constant as the voltage
drops.
(As opposed to a resistor!)

If you put your resistor (R405) across a real 28 volt supply, you don't get 40
amps.
(more like 70!) But even 40 amps at 28 volts is 1120 watts, a LOT of heat.

There's hardly a need to do this. You can find it already done in Kraus' _Antennas_. In the first edition, Chapter 3 is "The Antenna as an Aperture", which covers the topic. In the second edition, the topic is covered in several sections of Chapter 2. See in particular section 2-20, "Maximumum Effective Aperture of a Short Dipole" and 2-21, "Maximum Effective Aperture of a Linear [lambda]/2 Antenna".

You might have to refer back in the book a bit to get to Maxwell's equations, but they're there.

[snip]

I have already provided you with a reference and specific quotations from Balanis. I cannot do any better than that. Balanis uses conventional notation and describes well-known results. He appears to agree with the reference you have provided.

I can show you exactly how Balanis calculates the Aem of a short lossless dipole if you care to see it (page 83). Beyond that you'll have to read the book yourself.

First, he assumes that the current of a short dipole is constant and of uniform phase (because length << lambda). This give the total voltage induced by the field in the dipole (all amplitudes are peak, not RMS),

Vt = E . L

where E electrical field of the incident wave and L is the length of the dipole.

Next, for a uniform plane wave he writes the incident power density,

Wi = E^2 / 2n

where n is the intrinsic impedance of the medium (air or vacuum = 120pi = 377 ohms).

Then he uses the derived radiation resistance of a short dipole (see page 136),

Rr = 80(pi . L / lambda)^2

and the equation for the Aem of a lossless antenna (page 82),

Aem = |Vt|^2 / 8Wi . Rr

to arrive at the result: Aem = 0.119 lambda^2

Sometime in the mid to late 60s (perhaps 67-68?), there was a construction article in either Popular Electronics or Electronics Illustrated (I'm leaning towards Pop'tronics) for a two transistor (2N3053s???) QRP rig on 80 Meters. It may even have been the cover article. It was point to point wired in a 3x4x5" Bud box, rather than PCB. It used miniductor coils and I recall that there was a metal particial in the middle of the box with the Osc on one side and the PA on the other.

If someone can point me towards the Month/Year of that article, or has a copy of the magazine, I would greatly appreciate getting a copy.

Thanks!

I suppose, strictly speaking, that for a lossless antenna
constructed from a perfect conductor, no radiation strikes
the antenna, but rather the antenna guides the EM radiation
to the load.

Hello.
I have done almost exactly the same thing. I made my low-ohmmage/high wattage resistors myself using copper wire. Get a wire table that shows wire gauge vs. resistance per 1000', and calculate how much wire of a certain gauge to give your desired ohmmage. The table will also show recommended current for given wire gauge in both open air and enclosed.
I made a very low resistance resistor this way, to test a battery charger. It drew around 60 amps at 28 volts. I forget how much wire I used, several hundred feet I think; wound it in a 2' coil. I used a homebrew 4-wire ohmmeter using a constant current power supply to actually measure the resistance of the coil. Different manufacturers of copper wire vary the diameter of the wire slightly, so you have to fine tune the actual length to get the exact value you need.
The finished resistor worked fine; it got hot to the touch, but not hot enough to require fan cooling.
I've made low value/high current resistors this way a number of times.

There's a field strength E which induces V volts in the small antenna, say a small HIGHLY efficient loop. So put loss resistance = 0. The loop has a radiation resistance Rrad and an inductance L. X >> Rrad.

The loop current is V / (R + jX) amps. But there's no power dissipated in the loop. Any energy collected is re-radiated because the loop's only resistance is Rr. So insofar as the field is concerned the loop may just as well not be there.

Now break the loop and insert a tuning capacitor which neutralises the inductive reactance. There is now a far greater current flowing round the loop. It is Q = X / Rr times greater.

But there's still no power dissipated in the loop. Any energy collected must be re-radiated because there is no loss resistance in the loop, only radiation resistance. Again, insofar as the field is concerned, the loop may just as well not exist.

Now connect a matched receiver into the loop. Matched to the radiation resistance because we want to maximise the power input to the receiver. Receiver input resistance is Rr ohms.

The total resistance in the loop is now twice the radiation resistance. The loop current I = V / 2 / Rr amps and the power dissipated in the receiver is Square(V) / 4 / Rr watts. And obviously the same amount of power is re-radiated. But now the field is certainly aware of the existence of the loop. The field becomes very distorted in the immediate neighbourhood of the antenna.

So, the act of inserting a receiver into the loop, with a loss resistance equal to the radiation resistance, results in an enormous increase in energy extracted from the field - if you like - it really sucks it in. But that's quite normal.

In practice, the conductor and other loss resistances are no-where near zero. Even before the loop is tuned and the receiver included, the antenna extracts energy from the field and re-radiates only a small fraction of it. So the act of tuning and inserting the matched receiver does not have such a dramatic effect.

>

You are missing the point that what have needs to include
"effective relative to what?". Again from the same reference,
stutzman and thiele:

"The available power is found using the maximum effective aperature,
Aem, which is the __COLLECTING AREA OF THE ANTENNA_. The receiving
antenna collects power from the incident wave IN PROPORTION to
its maximum effective aperature:

P = S Aem"

So, the very first assumption used to derive anything states the
physical area is equal to the maximum effective aperature. 2pages
later, (pg 79), the following is stated:

"We will show in Sec. 7.3 that for electrically large antennas,
effective aperature is EQUAL TO OR LESS than the PHYSICAL
aperature area of the antenna Ap, which is expressed using
_aperature efficiency \epsilon_{ap}:

Ae = \epsilon_{ap} * Ap

From Sec. 7.3.2, pg 295:

Ae = \epsilon_{ap} * Ap 0<= \epsilon_{ap} <= 1

Aperature efficiency, \epsilon_{ap} is a measure of how efficiently
the PHYSICAL AREA is utilized

-- To make any comparison which is valid you need the following --

(1) A reference to use. You need the physical dimensions of some
antenna which is of optimal dimensions. My opinion is you get
the same result for any one you choose, but to eliminate any
misunderstanding and keep it simple, choose a dipole with
length = \lambda = 1 meter. Find the physical diameter that
gets you the closest to the value 0.119 m^2, or at least is the
smallest diameter you use before you lose signal. The derivation
assumed infinitely thin, which taken literally doesnt tell
you anything at all about a physical area.

A) The short form of the answer, starting with an ideal
dipole is:

Aem = Ap definition

The power collected by the antenna is:

Pr_ideal = Aem_ideal * S

The power received is also defined the same way:

Pr_short = Aem_short * S

Aem is independent of z, so a short dipole and the ideal
receive the same power iff Aem is the same for both since
S doesnt change. This is the same as saying Aem is independent
of length (you could instead say width, but then the
interpretation of effective lengths would be even more obscure)
Aem is independent of length, so must Ap be independent of
length as well since that's how it was defined from the start.
Hence, two dipole antennas can only be equivalent if the physical
areas are equal and the optimum value is given by the above.
A smaller physical area ALWAYS means smaller effective area.
By contrast, you can have a less than optimal antenna any
number of ways, so any antenna with a physical area equal to
the physical area of an optimal antenna of the same area
will have an effective area equal to or LESS than the ideal.

See below for a longer redundant version showing opportunities
to invert what you call your reference and therfore fail hold
the same things constant when _applying_ the formulae. (Not
mistakes in the formulae)

(2) Since there doesnt seem to be a dispute over the definition of
the effective aperature, calculate the power received from some
source radiating Ps isotropically into 4*pi:

Aem = Ap, Ap = Physical area, by the initial assumptions for
all of the derivations that don't seem to be in
dispute.

Pr = S Aem, Pr = received power, S = power density from
the poynting vector
describing the source

S = Ps/[4*pi*r^2]

So, taking the cross sectional area of a cylinder such that
the source distance is large enough to avoid integrating over
r, the area Ap = l*D and the power received is:

Ps l D
Pr = --------
4 pi r^2

(3) The effective aperature does not change by shortening the dipole,
but no where, is it claimed that the width remains unchanged. The
above sets a hard physical limit, but it requires real numbers,
so plug in the best case scenario, 0.119 \lambda^2 and assume
1 meter for \lambda. So, the width must be:

l*D = 0.119 * 1m^2

or D = 0.119 meters.

The power recieived is then fixed and related to optimal
real dimensions. Pr_ideal (through a redundant calculation
for the sake of being explicit) is:

Pr_ideal = Ps* 0.119m^2/[4*pi*r^2]

(4) repeating for your dipole of 3.33 mm x 2cm I get:

Ap = 6.67 x 10-5 m. For the sake of argument, I'll pretend I
don't the outcome, so suppose this is
equal to some effective max. aperature Aem
of an ideal dipole.

(5) Aem is unchanged, by definition, from changes to the length and
and the result in the ideal case relates Aem to the Ap
(actually, this is totally unnecessary, but since no one wants
to believe the definition means what it says, I'll "calculate"
the values. The definition Ap = Aem means any dipole, not just
the ideal case as it seems to have been assumed).

So, the short dipole is electrically equivalent to a 1 meter
dipole:

Aem(short) = Aem(ideal) ; by the definition

l*d = 6.67 * 10^-6 m^2 = D(ideal) * 1m

So the equivalent "ideal" dipole has a diameter of:

D = 6.67 x 10^-6 meters.

This is quite different from what was calculated for the ideal
dipole using the the theoretical estimate and applying the exact

same requirement that at a length of 1 m, the optimal ability
to collect power meant that the corresponding width as determinded
from Aem = Ap = 0.119 \lambda^2 had to be 0.119 meters.

(6) Continuing, the power received from your short dipole is found
as before:

Pr = Ps * Aem/[4 * pi *r^2]

= Ps* 6.67x10^-6 m^2 /[4 *pi*r^2]

(7) You're claim is that this is equivalent to the power received
by a dipole given by 0.119 \lambda^2. That was calculated
above to be:

Pr_ideal = 0.119*Ps/[4 pi*r^2]

The ratio indicates the optimized ideal dipole recieves an enormously
greater power than the short dipole. The reason should be obvious.
These two numbers compare two things that are not related to each
other a priori through whatever formulae were used to derive the
short dipole result you state, but you assumed they were equivalent.

In fact, they ARE related. What is the relationship?

Pr/Pr_ideal = 6.67x10^-5/0.119
= 5.6 x 10^-4

Your short dipole receives radiation equivalent to a dipole
1 meter long that collects no where near that which the area
given by what .119 \lambda^2 gives you. If I recall, the
difference is what you were calling an increase. You've
inverted the relationship, by calling those two power values
equal and introducing a constant multiplier which is subsequently
never removed. Whether it was explicitly overlooked or whether
implied in the text, that is where the confusion lies.

(8) You can save the entire set of superfluous steps by simply using
the definition Ap = Aem for the ideal case along with the assumption
(or really, forced property by decree in the texts) that Aem is
independent of length. That means Ap is independent of length
and by the assumption that preceded all any of the calculations,
that Pr = S Aem, Pr = S Ap, must be true.

Reg Edwards said some stuff about

>obviously the same amount of power is re-radiated. But now the field
>is certainly aware of the existence of the loop. The field becomes
>very distorted in the immediate neighbourhood of the antenna.
>
The "distortion" occurs because of what is NOT re-radiated.
It's an effect, not the cause. The total radiation striking
the antenna doesn't change. Any "distortion" is due to
having removed a fraction. It couldn't very well look identical
as it does with no antenna or you wouldn't have extracted energy.

>So, the act of inserting a receiver into the loop, with a loss
>resistance equal to the radiation resistance, results in an enormous
>increase in energy extracted from the field - if you like - it
>really sucks it in. But that's quite normal.
>

How about an enormous amount of energy that ends up in your receiver
rather than back in space. The same amount hits the antenna either
way.

>In practice, the conductor and other loss resistances are no-where
>near zero. Even before the loop is tuned and the receiver included,
>the antenna extracts energy from the field and re-radiates only a
>small fraction of it. So the act of tuning and inserting the matched
>receiver does not have such a dramatic effect.

Matching involves matching two things. Matching the antenna to
the impedance of the dielectric that surrounds it and matching
the receiver to the antenna. Matching to the surrounding dielectric
is the reason for the geometry. The optimal components to match
to the receiver are those which maximize the tranfer of the power
from the antenna.

Sorry Bilge, you are unnecessarily going off at half dozen different
tangents simultaneously.

I have provided a satisfactory explanation of the more APPARENT than
real power suck-in. There is no "enormous amount of energy" involved.
As I suggested before, just put some sensible numbers into the simple
equations. Don't let the thought of a little arithmetic put you off.

I've already posted it. See the other post where I show exactly
what I get by ignoring any of my simpler arguments and just
what keeps getting offered as demonstrating the opposite. I
get the same result I get every other way. The "Huge" was your
own wording, but in fact does describle the result with the values
I was given to work with. It also reinforces the idea that
plugging in numbers requires more effort than just invoking
some physical reasonableness, without necessarily doing anything
but confusing the issue. You should never calculate something
without knowing all of the qualitative features that went into
deriving the formulae.

When I last moved and only had a small space for qrp, I replaced several tuners and SWR meters with MFJ-971 and a rotary switch - works fine with my qrp rigs, my little Icom 725, and even my little 6m rig.

Source record: 61432

A tuner is not needed for QRP. Just put the right number of turns on
the PA output transformer, or the link coupling on the output tuned
circuit. No tuner, no loss.

Of course, tuner loss doesn't matter if the tuner is considered to be
an integral part of the transmitter, such as a Pi-tank output circuit.
A Pi tank inside the Tx box is just one of many forms of tuner.

By extension, why not define the transmission line as being part of
the transmitter. Full QRP power can then be applied right at the
centre of the dipole.

Perhaps QRP should be defined in terms of ERP = effective radiated
power. Tuner, feeder, antenna and ground losses can then be treated
in the same way as PA inefficiencies - they don't count..

[snip]

You appear to be confusing electrically large and small
antennas. It is true that the Aem of an electrically large
antenna cannot be greater than it's physical aperture area.
A short dipole (length << lambda) is not an electrically
large antenna. Its Aem is larger than its physical area.

This apparent confusion between large and small antennas
leads to your incorrect assumption that the Aem of dipoles
is never better than Ap, the physical area.

How does your reference define the term "electrically
large"?

I'm trying to locate an article from QST, early to mid 90's describing the use of an HP Plotter to directly print on copper boards. The article described how to modify a standard office supply store felt tip pen whose ink is resistant to standard etchant chemicals.

The plotter of course was driven by a PC to print the pattern on the board.

Any info would be appreciated.

I do not know what you mean by impact ironing-on process. If you are referring to the iron on process of transferring a printed image on to a copper clad board and then etching the board, then I suggest PnP Blue.

What you need to do is print your PCB image usig a laser printer (not ink jet) onto a PnP Blue sheet. The reason for the laser printer is that the toner consists of plastic particles that when melted by the heat in the printer form the black print. The PnP Blue sheet is then ironed onto the copper board. When cool peel the plastic backing off. I have had excellent results with this process - achieving line spacings of 10 mils. Note: the ironing process is a bit of an art - READ the instructions.

I have tried other iron on methods but PnP Blue has provided the most consistent results.

PnP Blue is available from

Techniks Inc.
P.O. Box 463
Ringoes NJ 08551
(908) 788-8249 for Orders

Last pricing I had it was 20 Sheets for $30 US.

An article entitled "Ironing Out Your Own Printed Circuit Boards" by
John Grebenkemper in the July 1993 QST gives details on a process using
plain-paper printouts from a laser printer or Xerox-type copier.

Prove it. So far, I've taken whatever definitions you or any
one else has put up, chased down them down to make certain the
I write down the correct relationships and gotten the same results.
Now. Skip these stupid definitions which are nothing but redinition
and redefinition and for a change, you show EXPLICITLY from first
principles that you can violate cauality, qed and the rest. I'm
not going to continue to invert and reinvert normalizations just
because nobody learned any physics and can't keep the normalization
straight. I cannot find a single reference that lets my violate
the same physics that applies to everything else. I don't know
why one small segment of e&m has some mysterious attraction as
a voodoo by people, that cant even keep the straight the difference
in radiation fields/real photons and static fields/virtual photons.
They dont interact with each other under any theory known in
this universe and if measurements indicated they did, people
would be climbing all over themselves to be the first to publish
an extension to QED. Now, I've posted hundreds of lines catering
to other people's wish to use terminology which only buries the
absolute numbers. State a result, in watts for antennas which arent
constructed backwards. Pick Width and Height. Determine the current
distribution and produce what you claim for the small dipole.
Do not use any infinitely thin anything, unless you plan to
show how infinity scales.

>This apparent confusion between large and small antennas
>leads to your incorrect assumption that the Aem of dipoles
>is never better than Ap, the physical area.
>
>How does your reference define the term "electrically
>large"?
>
Skip this relative to, normalized with, nonsense. Derive, from first
princles (maxwell's eqns) an ideal and short dipole. Produce the
angular distribution for the ABSOLUTE power as a function of
(r,\theta, \phi). At this point, I'm not going to waste time trying

to find out where someone has inverted a value or added something they should have subtracted. Having me hunt down another definition of something irrelevant every time someone doesn't like the last result could go on forever. Produce a self contained reason to have me believe this isn't just another wasted of effort. If you are correct, you hould be able to show it. There should be no reason to use any definitions which aren't obvious. Everyone knows what a current is, a watt is, a steradian is. For any fixed value of the poynting vector S, show the small dipole collects radiation in excess of S x Ap. Not in terms of voltages in the receiver, but straigt out watts on the antenna surface. Explain how you don't violate the optical theorem.

> Prove it. ....Skip these stupid definitions ....etc.

Mr. Bilge, believe it or not these people are trying to help you. The problem is that until the last day or so, no one understood what you were trying to say.

For the benefit of those who still think that they can explain to you the idea of "energy sucking", here is what Mr. Bilge appears to believe:

1. The maximum power that any antenna can absorb is limited by the flux in watts/meter-squared through the physical antenna.

2. There is a theorem in textbooks which says that the maximum power available to a short dipole is independent of its length.

3. Items (1) and (2) are resolved by a specially-contrived re-definition of a "short-dipole", where the physical width of the antenna grows as its length shrinks, so as to keep its actual area a constant.

4. The proponents of "energy sucking" are cynically ignoring this devious trick of re-defining the width of the antenna in order to make it appear that something peculiar is happening with the energy flow.

> does anyone know how to calculate the out put impeadance of this
output
> stage of a transmitter operating at approx 410Mhz
============================
Yes. Dead simple. The 15nH inductor is in parallel with the 10pF
capcitor. At 410 MHz they both have the same reactance of 38.7 ohms.
Their resulting parallel impedance is therefore extremely high.

Thiis leaves the impedance looking back into amplifier equal to
whatever the impedance is looking back into the transistor collector.
Your transistor manufacturer's data book will tell you that. It also
depends on the transistor's operating angle, class A. B or C. But
usually the transistor's internal impedance is high enough for the
device to be described as a current source. That is, its impedance is
very much higher than the amplifier's external load impedance.

Why do you want to know ? It doesn't usually matter very much.

Actually, incandescent lights are a lot closer to a constant current load than a standard resistor. The resistance rises as the temperature increases, so they make a pretty decent cheap "constant current" load.

One could also do it with lots of copper wire, as someone else noted. You can get 250 foot rolls of 12AWG "two conductor plus ground" house wiring cable for around $20 here in the US these days. It should be pretty safe to parallel two of the conductors, if you don't leave it tightly coiled, and put 20 amps through each. 250 feet of #12 should get you about 0.4 ohms; two in parallel would be 0.2 ohms. 40 amps is pushing it for a single conductor, but might be OK if you had the wire stretched out in free air: it's rated for 20 amps inside insulated walls. But 40 amps is FOUR times the power dissipation per foot.

Cheers,
Tom

Todd,

I don't have anything like you want but I would suggest you investigate something like no. 14 wire and wind your own.

Your problem is something like my microwave problem. Some years ago I read an article that made me realize that microwaves were measured with a pocket ruler instead of a 100' tape ruler but was well within my grasp.

Good luck on your project.

David

Hi Dave,

I remember the article because I considered building it when I was first licensed. That should mean it came out in 64 or 65.
My Elmer supplied me with a homebrew transmitter that worked well so I didn't attempt it. Anyway, I think it was published in Popular Electronics. Newer designs in books such as SOLID STATE DESIGN FOR THE RADIO AMATEUR would probably work better. Of course you may have other (nostalgic?) reasons for building it. Unfortunately, I don't know where to find a copy. 73

Jan OM,
My TS820 is now about 25 years old. I bought it new. I work only CW,
and Amtor/Pactor ARQ FSK. It has thousands of hours on it now, with all
original 12BY7 amd 6146 tubes. I average about 8-10 hours a week on
the air. Amateur service is normally so light that tubes can last a
lifetime with care. In my opinion, many if not most tubes are
unnecessarily replaced in amateur gear.

73 and GL,
Don, W6JL

pleased to read this, OM. It is also my experience that - provided you
know how to treat it - the tubes will last.
I've been called by several amateurs who have bought some tube type
equipment, and demand spare tubes, an owner of Drake R-4C demanded
twice the amount of tubes that was in the receiver, but of course I do
not help fools
it is just rididculous, they don't know what the device is, I have lot
of ex-German equipment with over 60 years old tubes, many has been in
service since 1940-42, and for my old Drake 2-B I only replaced 6BE6
and another type for the first 10 years of use

When they do go 'soft' on you -- you'll see it first and most
dramatically on 10M first. I've spent most of the last decade
on 40M and 15M with my TS-520. Last year, as the sun spots allowed,
I went up to 10M and started having fun there, too -- but,
getting no more than 10 watts, or so, out of the 6146's.
I still have 'reasonable' power out on 15M, and 'full' power out
on 40M -- but it's now QRP on 10M.
Which is ok -- QRP works just fine on 10M when it's open.

I an using the original Tungsol 6550s in my Central 100V (circa 1958-59) which I used for years in long winded key down RTTY. The secret to that unit's tube's survival was the Screen Grid overload relay that would kill the screen voltage anytime the PA was abused by a nasty VSWR or overload or what ever. A simple scheme that would save the lives of many tubes if used. Of course the 6550 with 35 watts of plate dissipation also contributed to its long life as well. Not a 6146, but out of the same 6L6 family.

FWIW (Since this technique works best for solid
conductors...)
Use the flat jaws of needle nose pliers to crunch the
insulation. It will (cold flow) seperate at the contact
lines. Peel back the two flaps and snip off.

Hi Derek,

check http://run.to/pcb

we make double side PTH, FR-4 1,6 mm (0,062") 160x100 mm (6,3x3,9")
prototypes with solder mask and silkscreen component mark for only
$26,00 in single quantity. shipment in 3-5 working days

3174. Howto kill Transformer Noise ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-04-18 00:00:00 UTC

Hello, all.

I have Astron RS-20A Power Supply.
Ever since I acquired this P/S, it produces 60 Hz HI-FI audio.

I even have changed its positions, ex. upside-down, sideside up, but nothing helps.
After open up the case, I have found out that revets holding Transformers are loosened a little bit.

I have sent numerous E-Mail to Astron, they remain in silence.

Anybody knows how to stop this noise ? It really is annoying when working on Midnight DX specially.

Thanks in advance.

John / N2FNO

Get a half gallon of varnish from an electric motor shop. (They dip motors
with windings in it
to lock things in place) Dip your transformer in it and bake it at 300
degrees for 45 minutes..
(Send the wife on a long shopping trip) I have used this to quiet
saturating core inductors.
If the transformer is that noisy I would lean on Astron and try to get them
to give you a new
transformer.

This technique doesn't sound or look very sophisticated, but often works. With a medium sized hammer, while the transformer is buzzing, give it a tap on a corner. If no effect try another corner until you hear the noise decrease. Keep tapping and you may find it goes away. It's an old techie trick that often works.

There are two types of 60 Hz hum from a transform. The first is due internal plates vibration and can be cured as indicated in this thread with varnish, enamel (I've used colophony rosin with great success but you must be very careful when melting it because it is highly inflammable). The second type is due external ferromagnetic material vibration into the magnetic field from the transformer. This is easily cured by dumping the vibration or by keeping the transformer away from iron sheets and plates.
